National Transportation Research Center

DOE Vehicle Technologies Office

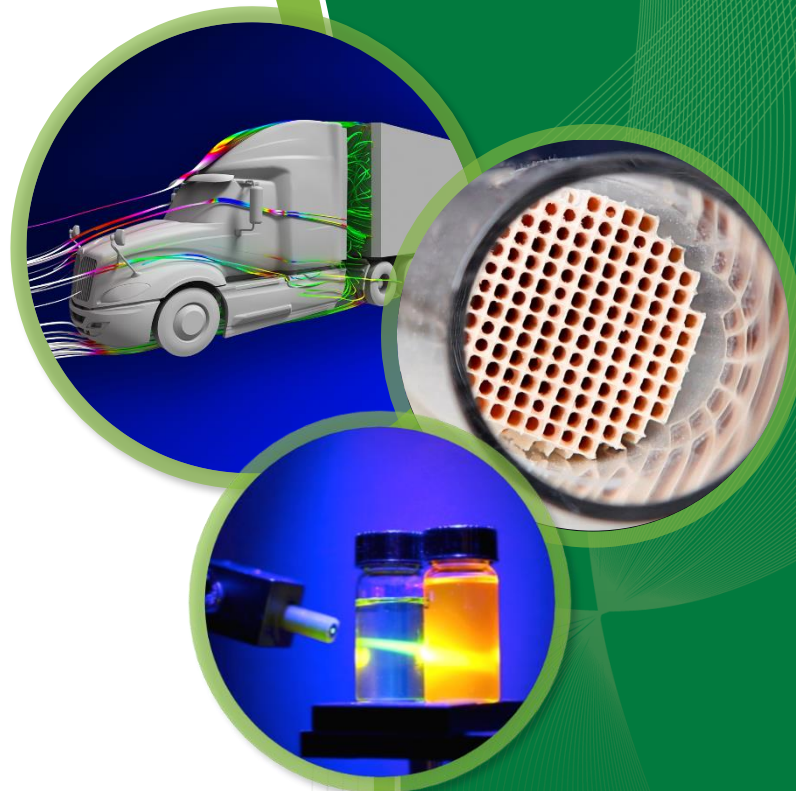

Annual Merit Review & Peer Evaluation Meeting

June 20, 2018; Washington, DC

DOE Managers:

Gurpreet Singh, Ken Howden

This presentation does not contain any proprietary, confidential,  
or otherwise restricted information

# Overview

## Timeline

- Year 3 of 3-year

## Budget

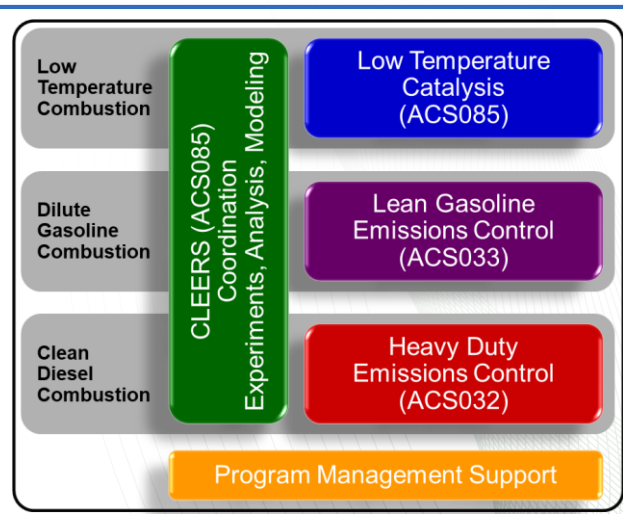

- 1:1 DOE:Cummins cost share
  - In-kind Cummins contribution
- FY18 DOE Funding: \$300k
  - Task3: Diesel Emissions Control
  - Part of ORNL project: “Enabling Fuel Efficient Engines by Controlling Emissions” (2015 VTO AOP Lab Call)

## Barriers

- From DOE VT MYPP:
  - 2.3.1.B: Cost-effective emission control
  - 2.3.1.C: Modeling for emission control
  - 2.3.1.E: Emissions-control durability

## Partners

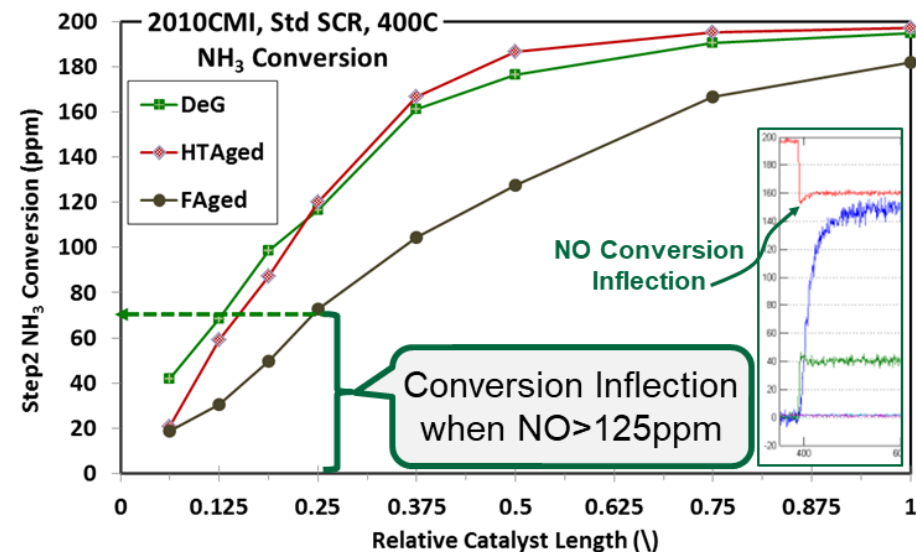

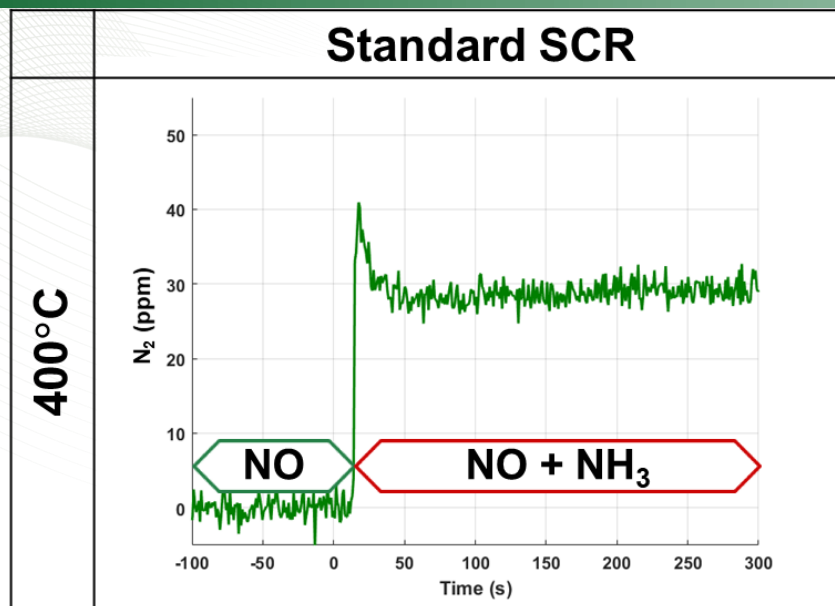

- ORNL & Cummins Inc.

# Milestones

FY	Qtr	Milestone & Objectives	Status
2018	1	Demonstrate an experimental method for characterizing relative rates of components steps of a global SCR mechanism	complete

# Background: Using Transients to Advance Catalyst Technology

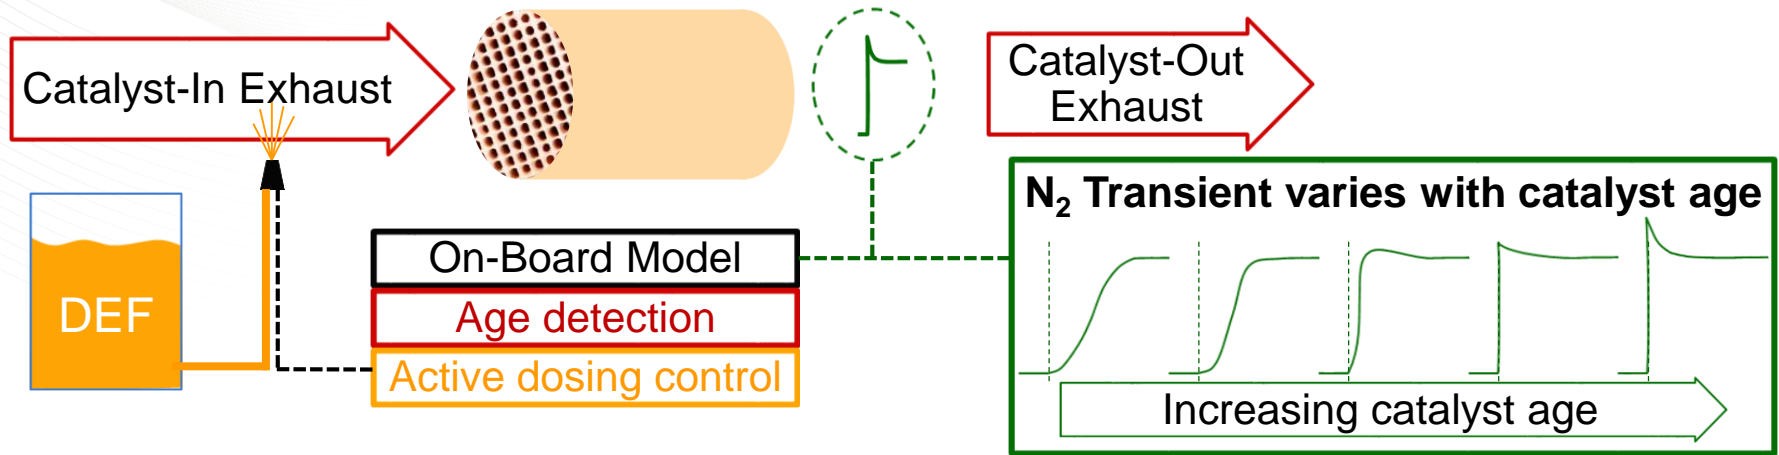

Partridge, et al., 2015 CLEERS Workshop

- Conversion Inflections (CI) can occur with Cu/SCR catalysts at SCR onset
  - Fast conversion onset & Slower conversion degradation to Steady state level
- SCR-onset CI has been observed for different Cu-SCR catalysts
  - Cu-Beta, Cu-CHA
- CI may be useful for monitoring catalyst ageing
  - Systematic CI progression with ageing: axial & transient at fixed axial position
- Not due to NH<sub>3</sub>-coverage inhibition as with Fe-SCR (see Tech. Backup Slides)
- CI is not captured by predictive Cu-SCR models (shown in FY17 AMR presentation)

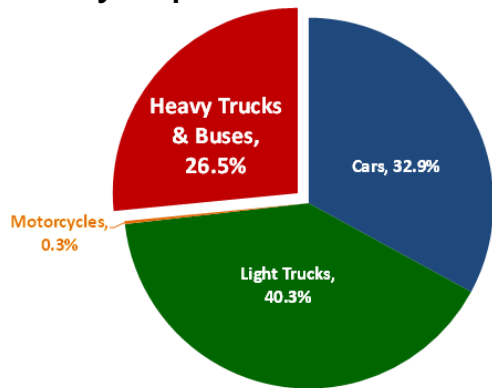

# Objectives

- Improve transient performance of SCR models
- Understand how field ageing impacts SCR reaction network
- Enable aged-state sensing to optimize catalyst performance

# Relevance

- Better catalyst performance allows engine to be optimized for fuel efficiency

# Research Path from Observation to Improved Fuel Economy

Transient step response of individual & combined Cu-redox half-cycles

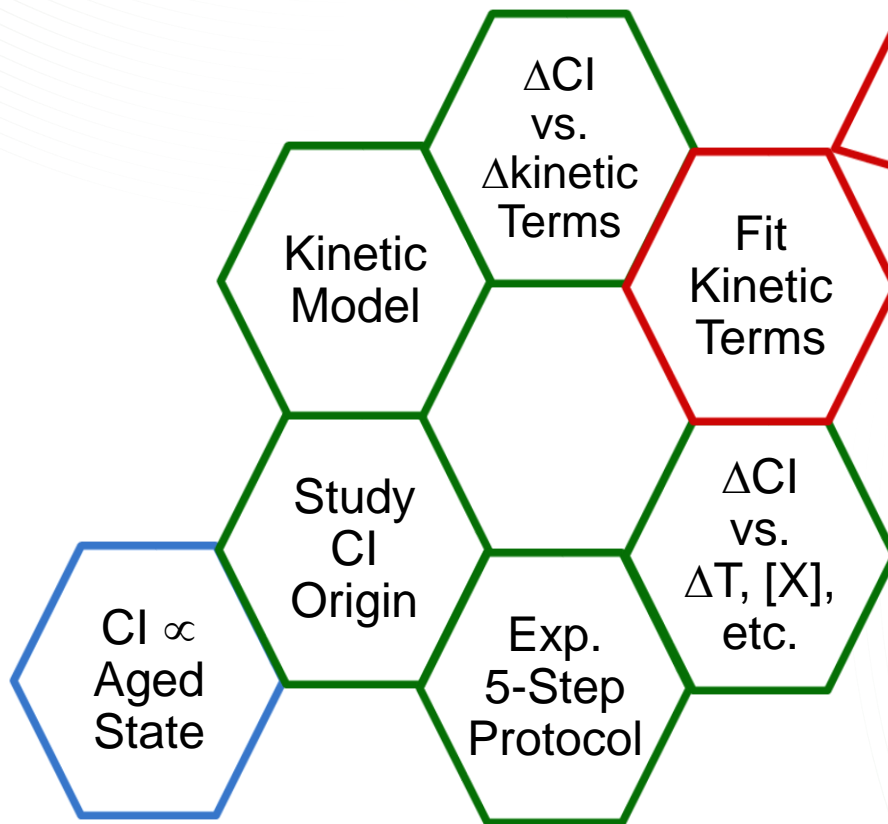

# Research Path from Observation to Improved Fuel Economy

Onset transients vary progressively with environmental conditions

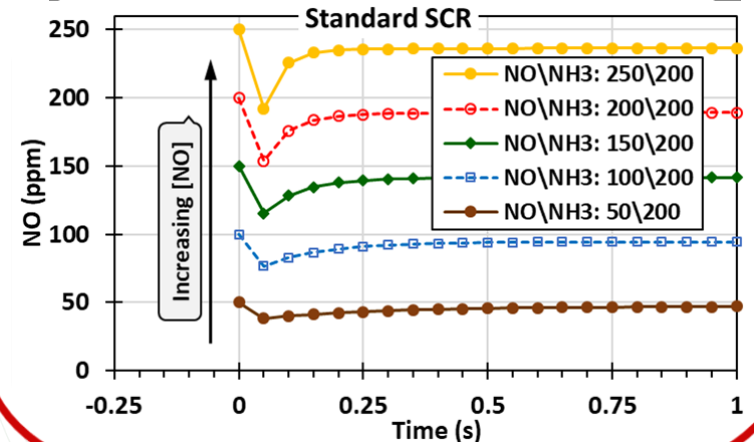

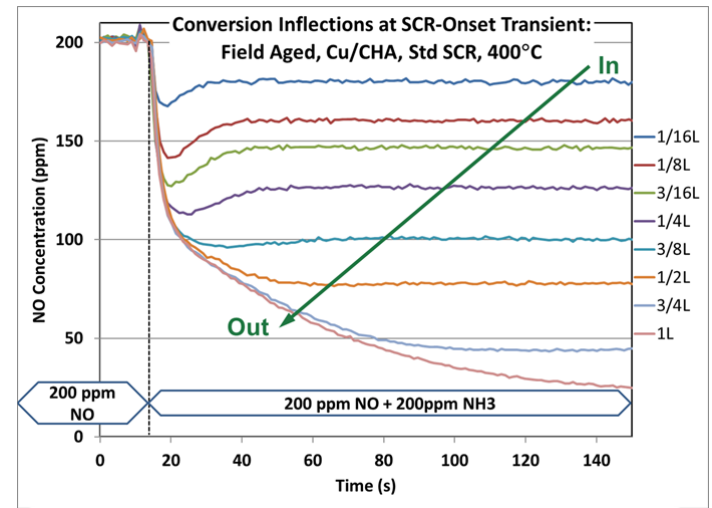

# Research Path from Observation to Improved Fuel Economy

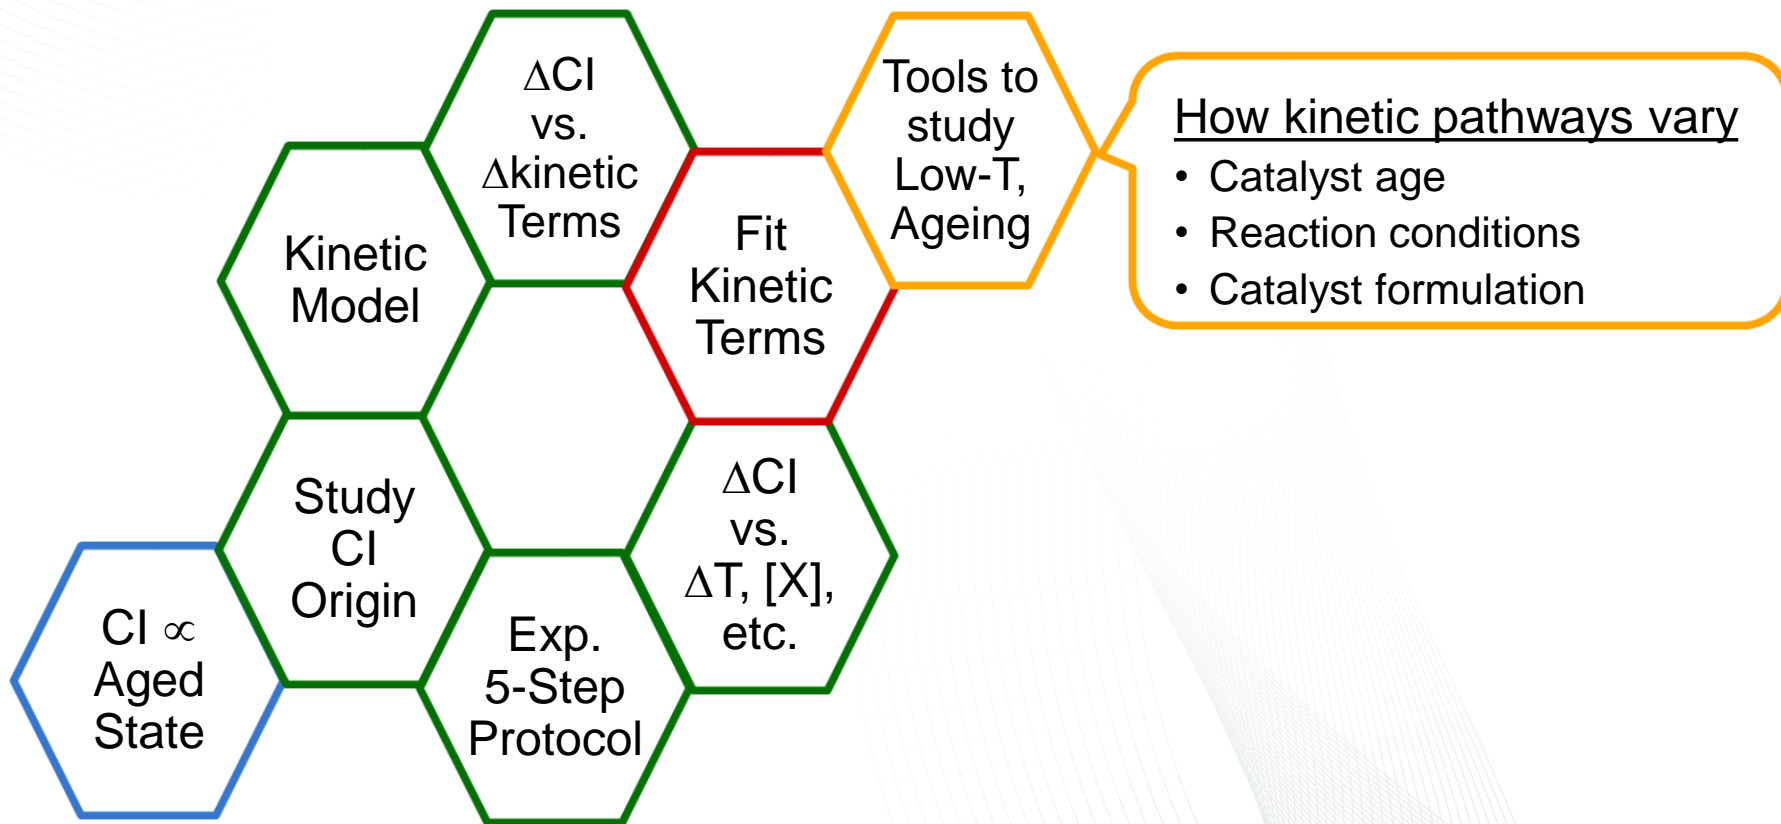

## Model & measurements trend

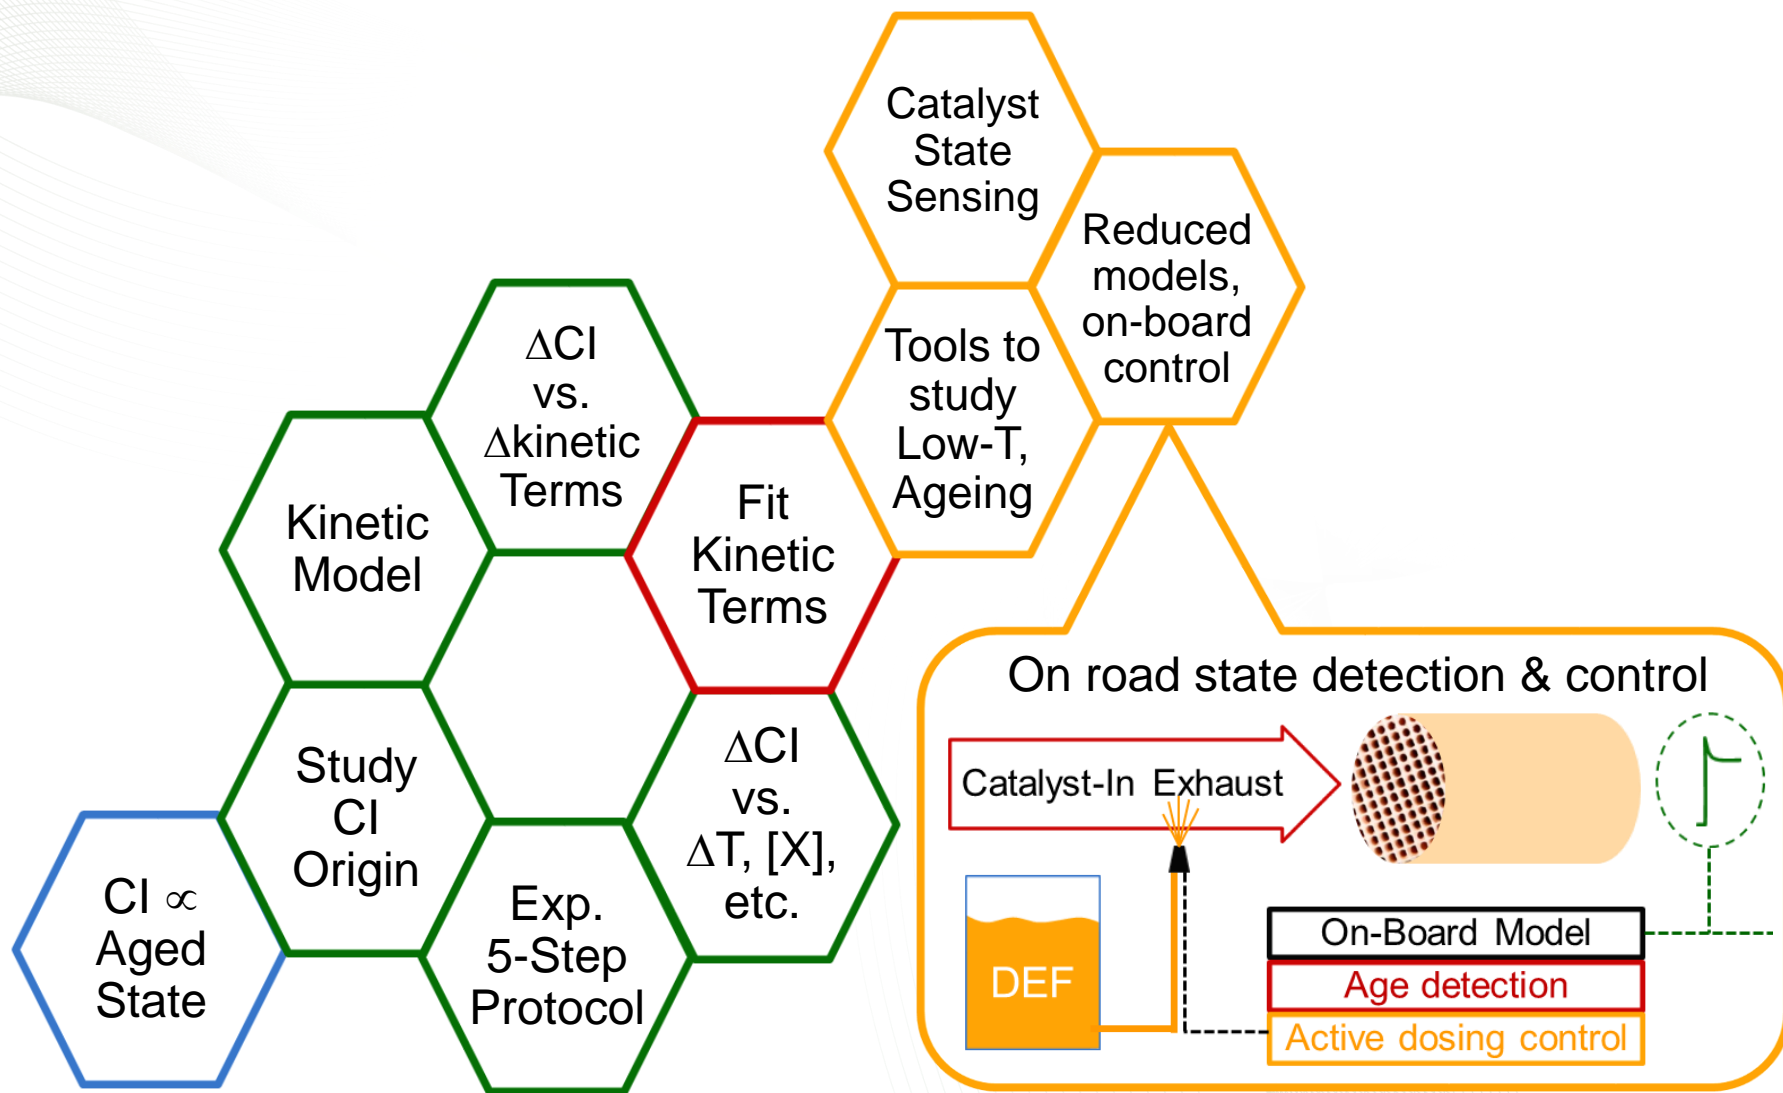

- CI origin relates to Cu half cycles
- Use Exp.-Modeling method to determine kinetic parameters

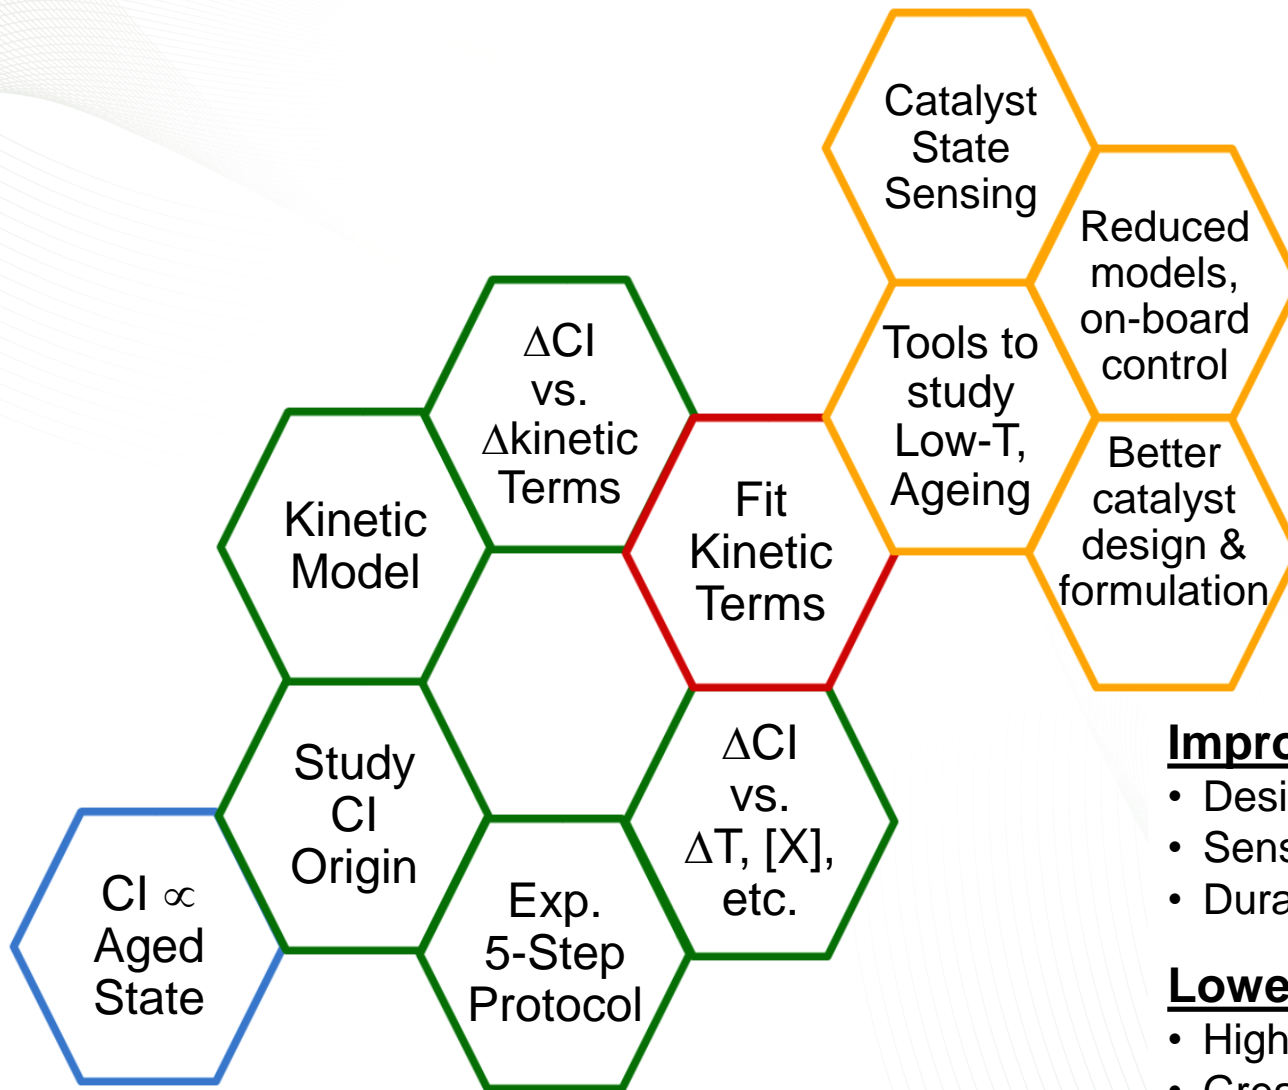

# Research Path from Observation to Improved Fuel Economy

# Research Path from Observation to Improved Fuel Economy

# Research Path from Observation to Improved Fuel Economy

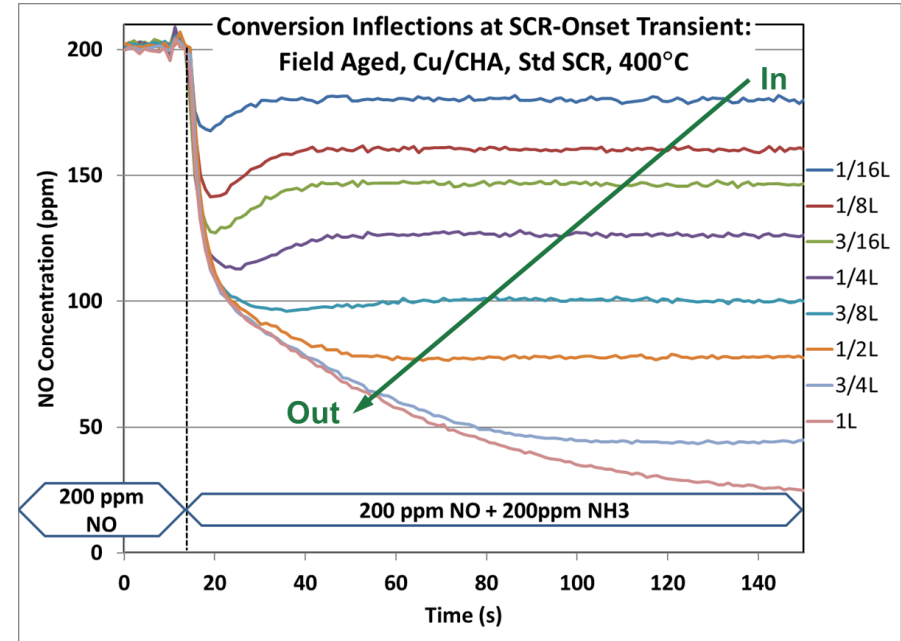

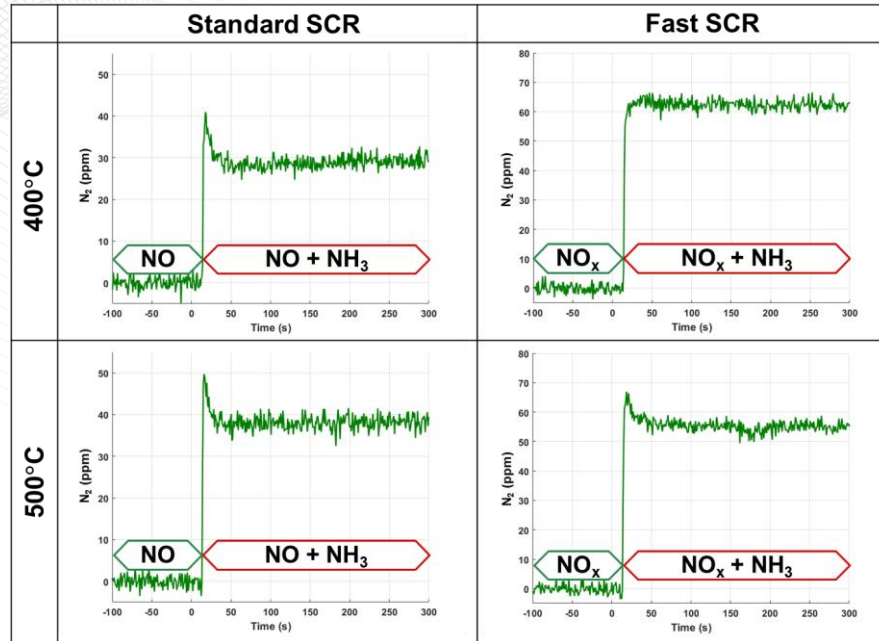

## Improved aftertreatment:

- Design & cost
- Sensing & control
- Durability

## Lower engine margins:

- Higher engine-out emissions
- Greater fuel economy
- Better engine durability

# SCR-Onset Conversion Inflections Vary with Conditions

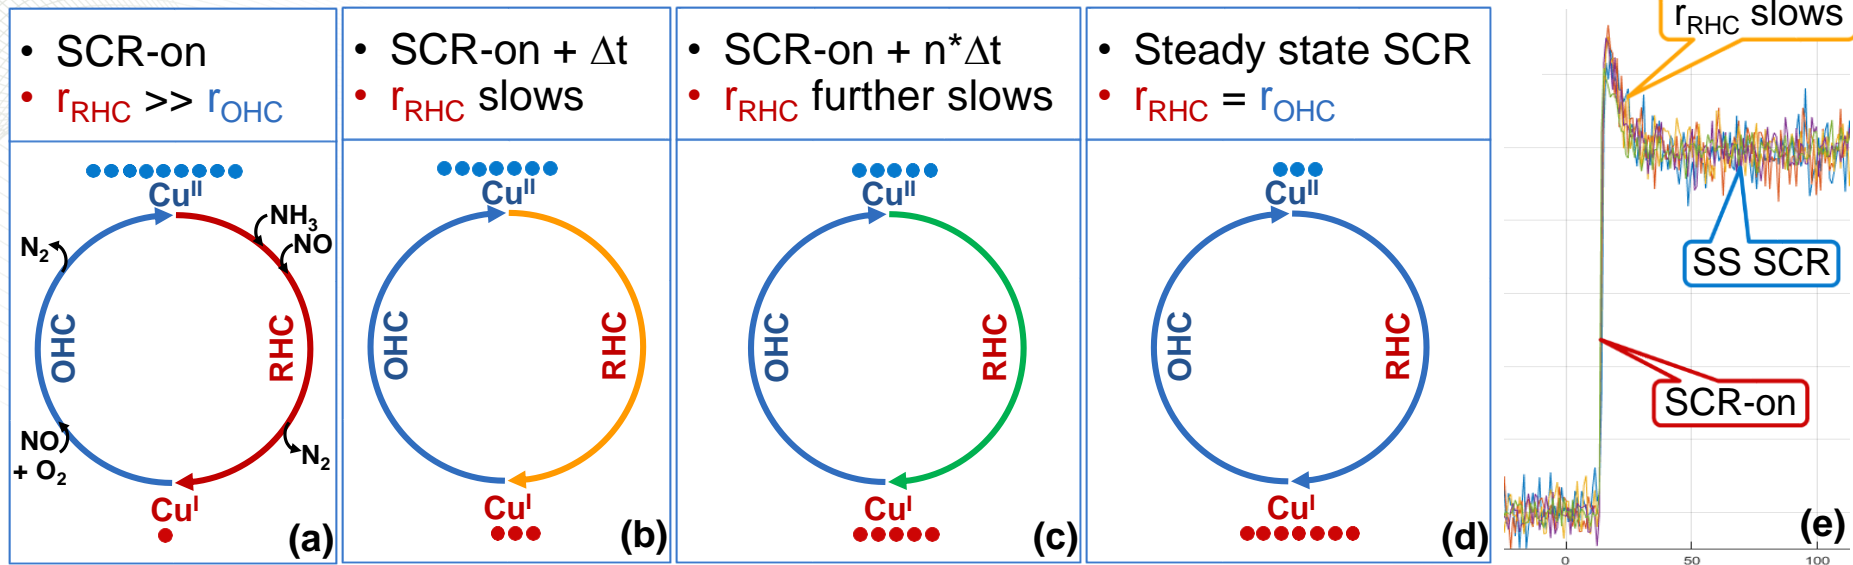

- CI nature varies with SCR type, temperature & along catalyst axis
  - More apparent for Standard SCR, at higher temperatures, and at catalyst front
  - Only apparent with Fast SCR at higher temperatures

*Study CI to understand its origins*

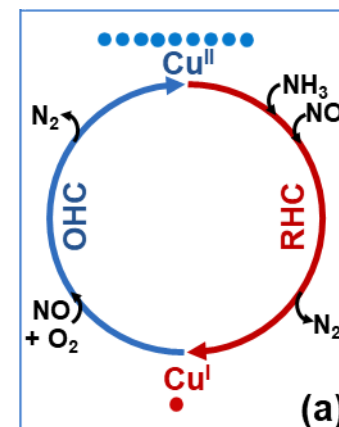

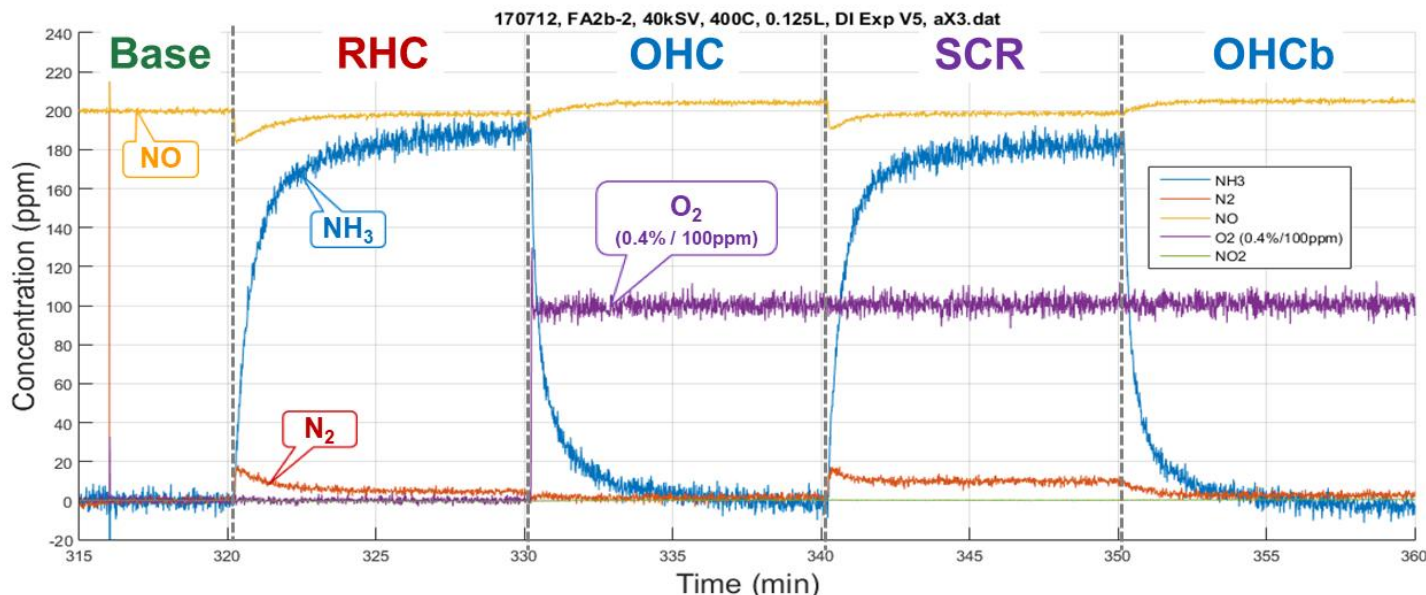

*Apply CI to improve SCR knowledge & predictive models*

# Conceptual Model of Cu/SCR CI Origin

- Cu SCR can be viewed as cyclic Cu reduction and oxidation
  - RHC: Reduction Half Cycle** – oxidized Cu ( $\text{Cu}^{\text{II}}$ ) is reduced to  $\text{Cu}^{\text{I}}$
  - OHC: Oxidation Half Cycle** –  $\text{Cu}^{\text{I}}$  is reoxidized to  $\text{Cu}^{\text{II}}$  completing the cycle
- Half-cycle rate imbalances induce CI at SCR onset
  - CI occurs when the RHC rate is faster than the OHC rate;  $r_{\text{RHC}} > r_{\text{OHC}}$
  - $r_{\text{RHC}}$  progressively slows to match  $r_{\text{OHC}}$  at steady state
- Half-cycle kinetic model was formulated & exercised to investigate CI nature

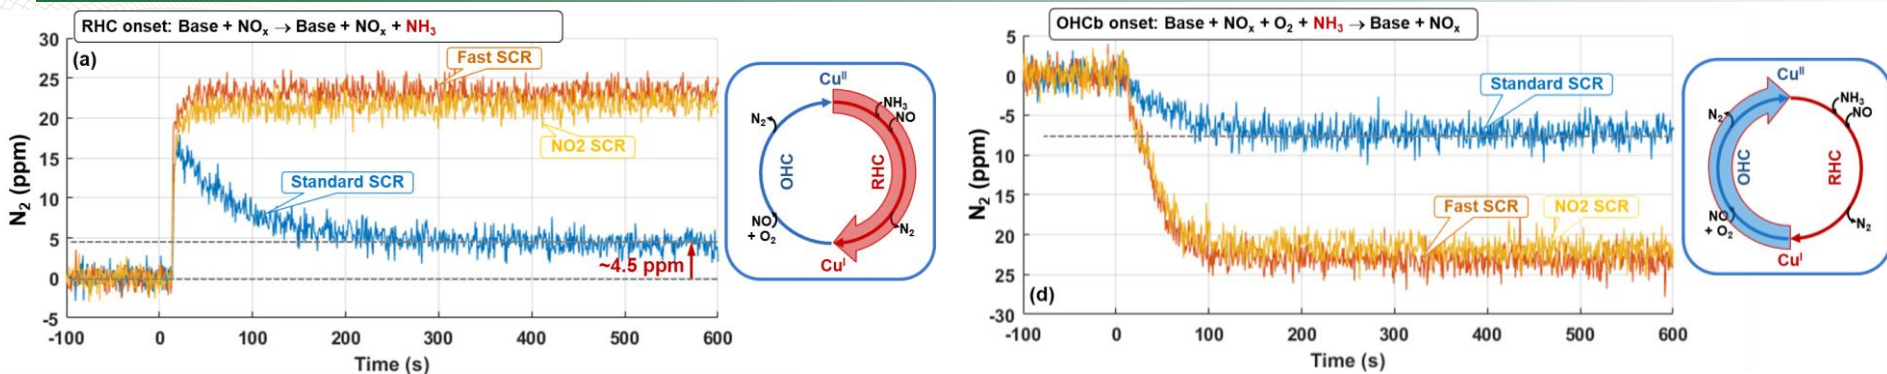

# Measuring Individual & Combined Half-Cycle Transients

- Experimental 5-Step protocol probes SCR half-cycle components
- Individual RHC, OHC & SCR transitions investigated
  - Step 1 - **Base**: 5% H<sub>2</sub>O + 200ppm NO<sub>x</sub> in Ar
  - Step 2 - **RHC**: Base + 200ppm NH<sub>3</sub>
  - Step 3 - **OHC**: Base + 0.4% O<sub>2</sub>
  - Step 4 - **SCR**: Base + 0.4% O<sub>2</sub> + 200ppm NH<sub>3</sub>
  - Step 5 - **OHCb**: Base + 0.4% O<sub>2</sub>

Transient nature reflects the half-cycle kinetic parameters

# Transient Response Probes Differences in Half-Cycle Kinetic Parameters and Reaction Pathways

- Transient response differs for RHC & OHC half-cycles
  - Reflects half-cycle-specific kinetics
- Transients differ with SCR type (Standard, NO<sub>2</sub>, Fast)
  - Reflects different reaction pathways
- SCR shows additional variations (see Tech. Backup Slides)
  - Reflects combined impact of simultaneous RHC & OHC

Use transient measurements to quantify RHC & OHC kinetic parameters

# SCR Models Formulated Based on RHC & OHC Half-Cycles

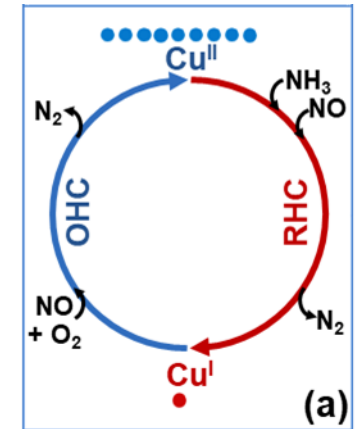

## Standard SCR

$$r_{\text{RHC}} = k_{\text{RHC}} \cdot [\text{Cu}^{\text{II}}] \cdot [\text{NO}] \cdot (\theta_{\text{NH}_3})^{\sim 0} \cong k_{\text{RHC}} \cdot [\text{Cu}^{\text{II}}] \cdot [\text{NO}]$$

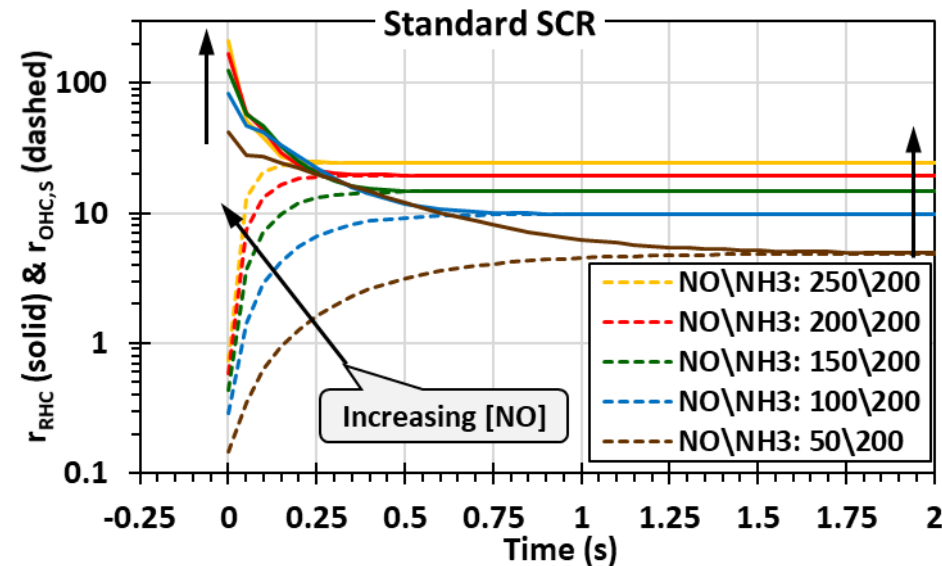

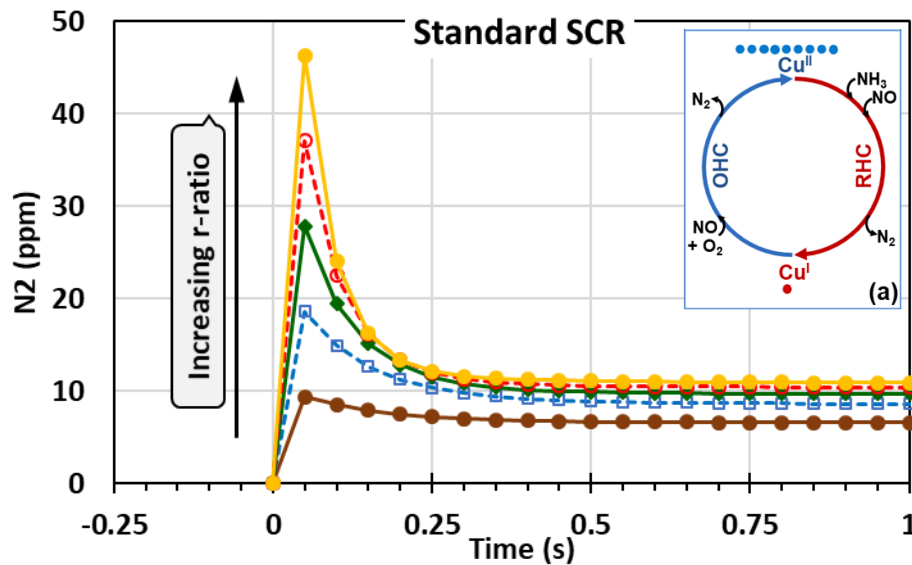

$$r_{\text{OHC}} = k_{\text{OHC}} \cdot [\text{Cu}^{\text{I}}]^2 \cdot [\text{O}_2] \cdot [\text{NO}]$$

- Half-cycle models formulated for Standard & Fast SCR (see Tech. Backup Slides)
  - Many different ways to formulate
  - Half-cycle kinetic parameters to be determined
  - Correct combination will accurately predict onset-transient response
- Exercise model to study transient CI nature
  - Origin
  - Variation with model formulation & kinetic parameters
  - Consistency with experimental trends

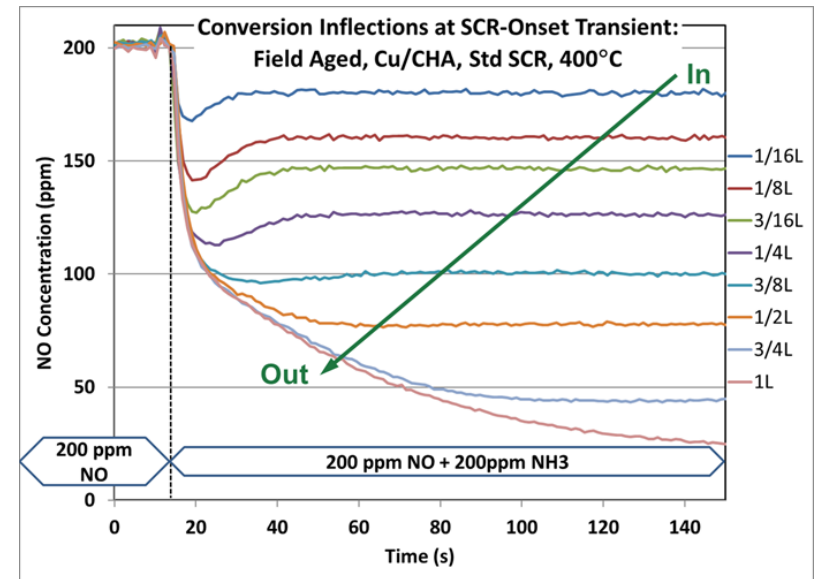

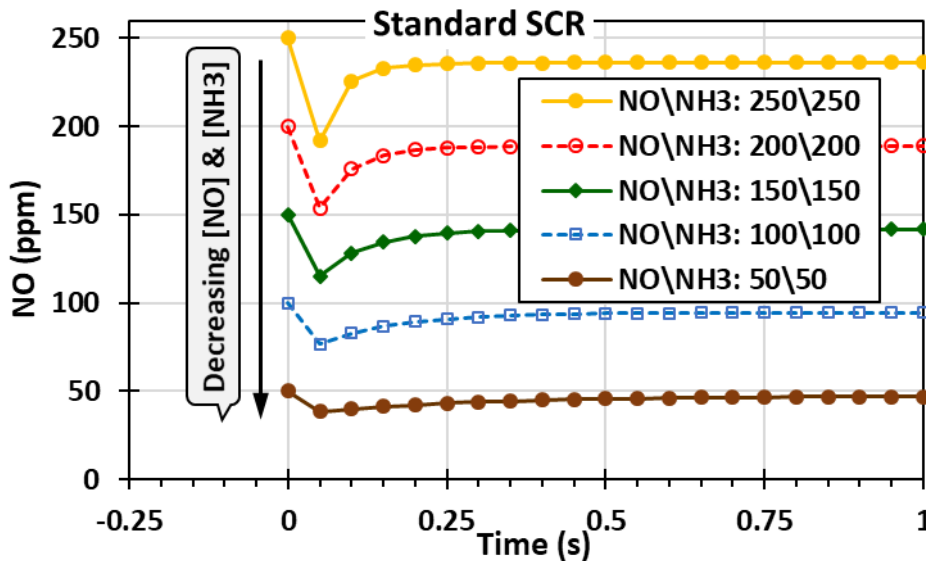

# Model Predicts Systematic CI Transient Variations

- CI becomes more distinct with increasing half-cycle rate imbalance
  - $r\text{-ratio} = r_{RHC} / r_{OHC}$
- Half-cycle rates converge faster with increasing [NO]
  - Rate convergence is consistent with conceptual model
- Many trends useful for guiding predictive-model development
  - CI increases with temperature
  - Stoichiometry transient reflects varying dominance & balancing of half cycles

**CI nature varies in consistent way with half-cycle kinetic parameters**

# Model Trends are Consistent with Measurement Trends

- Predicted NO CI trends are consistent with spatiotemporal measurements
    - Greatest CI at catalyst front
    - CI degrades along catalyst as NO-conversion progresses
  - Predicted CI temperature trends also consistent with measurements
- Consistent trends suggest CI is due to half-cycle rate imbalances
  - Proposed Cu-redox model appropriate for describing SCR transients
  - Suggests joint model-measurement study to determine SCR kinetic parameters

# Remaining Challenges & Future Work

## Key Challenge:

- Efficient catalyst performance under aged & low-temperature operating conditions
  - How does ageing impact SCR reaction network
  - Mechanistic impact of 'low-temperature' SCR formulations

## Future Work:

- Protocol experiments to characterize transient nature
  - Temperature, composition & stoichiometry dependence
- Determine RHC & OHC kinetic parameters
  - Formulate & tune SCR redox model using measurements
- Analyze how parameters are impacted by ageing and composition
  - Analyze various catalyst samples: baseline, aged, composition
  - Sensitivity of each half cycle, and parameter
- Use insights to advance catalyst technology
  - Improved predictive models for design & on-road control
  - Methods for catalyst-state sensing
  - Improving catalyst formulation

Any proposed future work is subject to change based on funding levels

# Collaborations & Coordination

- **Cummins**

- Project Partner, Saurabh Joshi (Co-PI)

## Teamwork & Roles

- **Interactions with technical community**

- 1 archival publication

W.P. Partridge, S.Y. Joshi, J.A. Pihl, N.W. Currier (2018). “New Operando Method for Quantifying the Relative Half-Cycle Rates of the NO SCR Redox Cycle Over Cu-Exchanged Zeolites,” Applied Catalysis B: Environmental. doi.org/10.1016/j.apcatb.2018.04.071 ; Available online 1 May 2018

- 2 invited book chapters
- 4 presentations (2 invited)

# Responses to 2017 Review Comments

## Recommendations:

- A more demonstrated understanding of differences between CI predictions and measurements is needed
- Show how CI phenomenon can be modeled and related to OBD or dosing strategy
  - *CI model has been focus this year, and shown in AMR presentation and publication*
  - *These results explain the differences noted in the '17AMR presentation, and provide a consistent CI understanding between measurements and model*
  - *Follow-on work will focus on detailed model based on the Cu half cycles*
  - *Out-year research will focus on applications for state assessment and control*
    - *basic evidence and concepts for this have been shown in previous presentations*
- Give more detail
  - *More detail has been provided this year in Tech. Backup Slides*
  - *Publication will provide more detail than is possible in presentation*
- Study range of SV
  - *Spatially resolved measurements cover a range of effective SV*
  - *E.g., 1/8, 1/4 & 1/2L locations have 8x, 4x & 2x, respectively, SV of the 1L location*
  - *SV can be swept in future detailed model for comparison to these measurements*
- Cummins interest is unclear, & suggest partner to focus on extracting non-proprietary content for general use
  - *CMI did all the detailed modeling presented last year*
  - *CMI & ORNL jointly develop and implement the research plan*
  - *The half-cycle kinetic model is completely open and has been published*
  - *The project has an excellent record of extensively sharing results with the VT community*
  - *The project did share performance measures of the CMI corporate SCR model relevant to the CI study; this has value beyond the CI application and those requiring access to the model details*

# Summary

## • Relevance

- Project work enables improved catalyst knowledge, models, design, OBD & control
- This reduces catalyst system costs & required engine-efficiency tradeoffs
- This in turn enables DOE goals for improved fuel economy

## • Approach

- Develop & apply diagnostics to characterize catalyst nature
- Analyze data to understand details of catalyst functions, interrelations & ageing impacts
- Develop catalyst-state-assessment methods & predictive catalyst models

## • Technical Accomplishments

- Experimental method for studying half-cycle origin of CI developed and implemented
- Half-cycle Cu-redox SCR model developed and exercised to study CI nature
  - Dependence on various kinetic parameters and reaction conditions shown
- Step-Response method demonstrated for formulating, tuning and validating SCR models
  - Applicable for catalyst-state assessment & enabling more robust predictive model

## • Collaborations

- Communicate results with Crosscut team & community via presentations & publications
- Coordination & collaboration with other DOE projects to maximize benefit

## • Future Work (Any proposed future work is subject to change based on funding levels)

- Develop SCR model with improved transient response based on RHC & OHC half cycles
- Apply new Protocol and Mode to gain insights into SCR ageing mechanisms

## *Technical Back-Up Slides*

# Project Approach

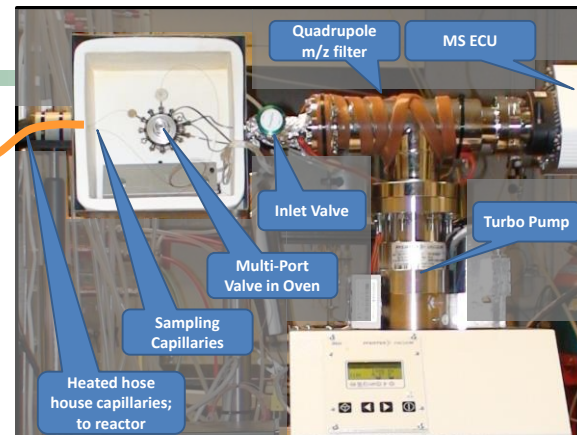

## Catalyst Samples

- Commercial Cu/CHA
- Cummins brings supplier knowledge
- Representative field-aged samples
  - Typical of 100s of field-use samples

## FTIR

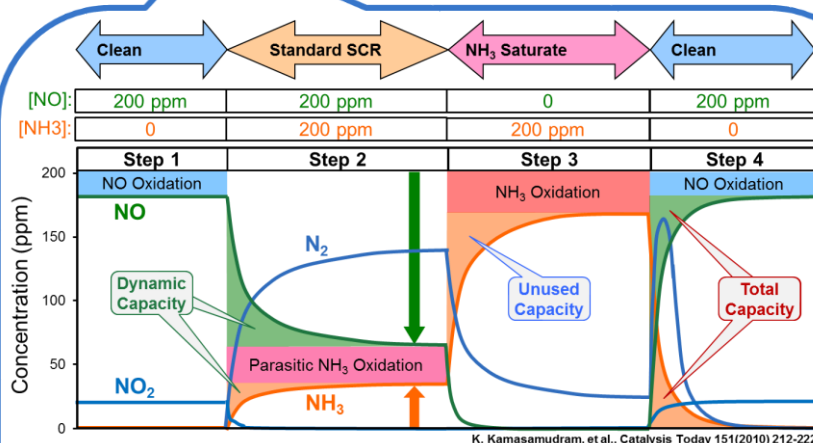

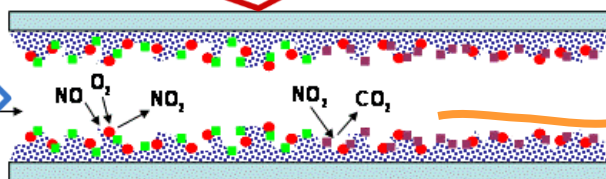

- Effluent species

## SpaciMS

- Spatial & temporal mapping
- NO, NH<sub>3</sub>, N<sub>2</sub>, NO<sub>2</sub>, N<sub>2</sub>O, other
- 1/16, 1/8, 1/4, 1/2, 3/4, 1L...locations

Gas Mix In

## 4-Step & Other Protocols

- Different T & species combinations
- Steady state & transient analysis
- Probes specific reactions & functions

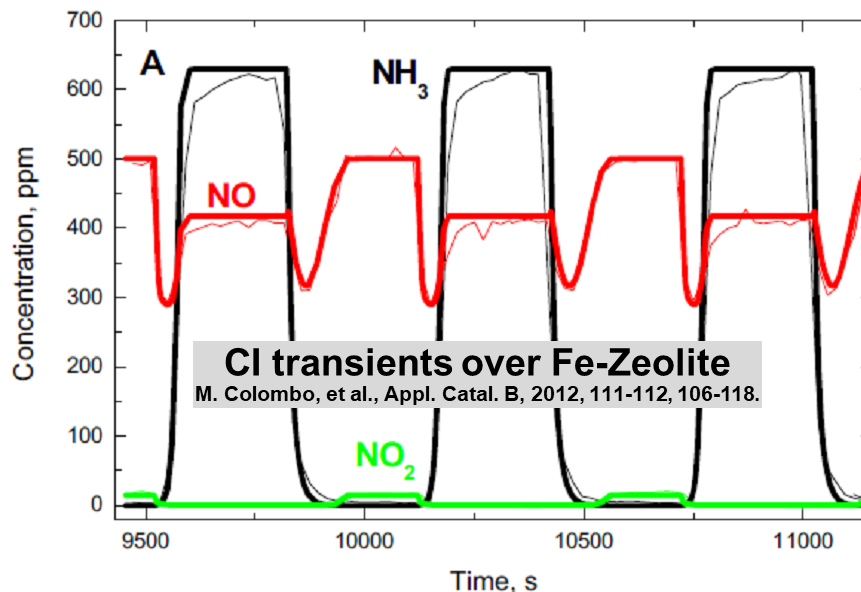

## Predictive Catalyst Models

- Cummins brings extra-project knowledge
- Project focuses on data for critical assessment & insights for improvement

## Enabling Project Contributions

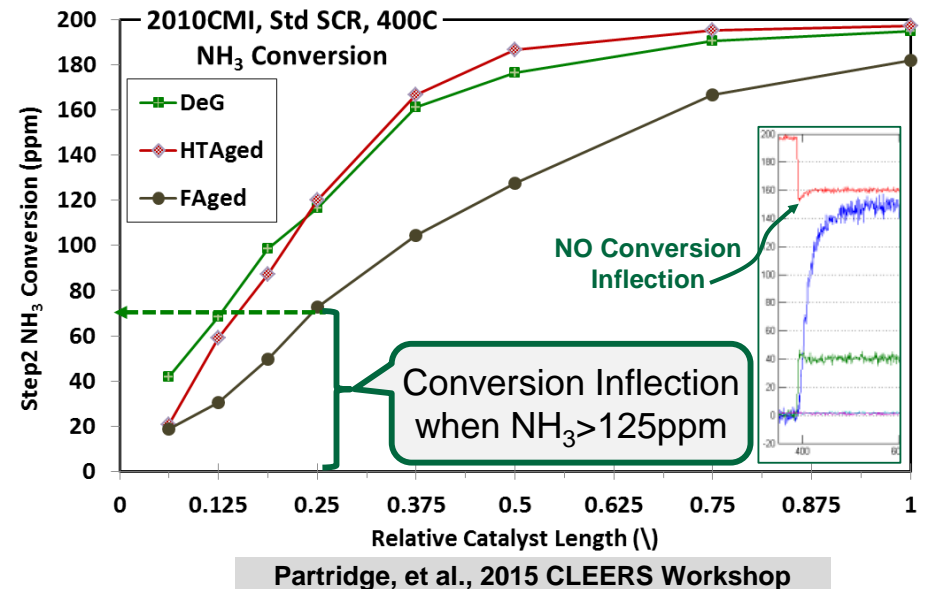

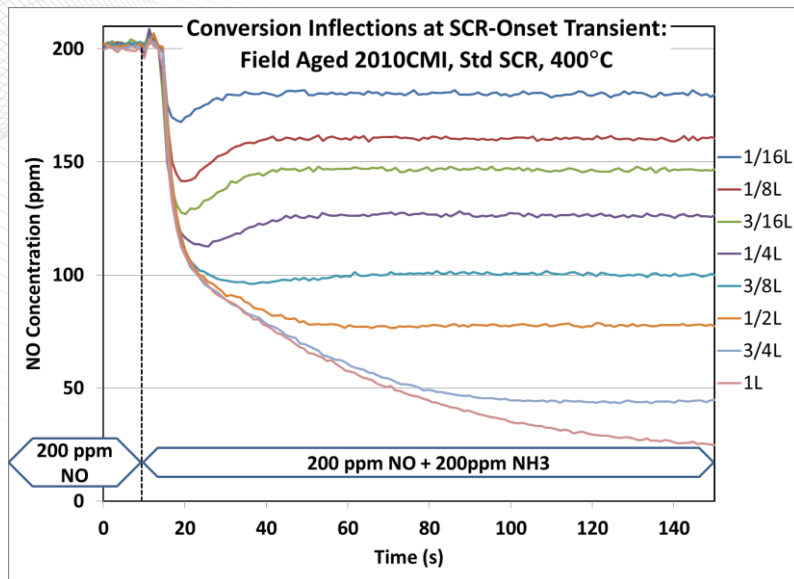

- Functional relationships & ageing impacts
  - Insights for improved modeling & state sensing
- Catalyst-state sensing
  - Sensing, OBD, efficiency, durability
- Robust & accurate predictive models
  - Design, efficiency, control, durability

# NH<sub>3</sub>-Coverage Inhibition Dynamics with Fe/SCR Catalysts

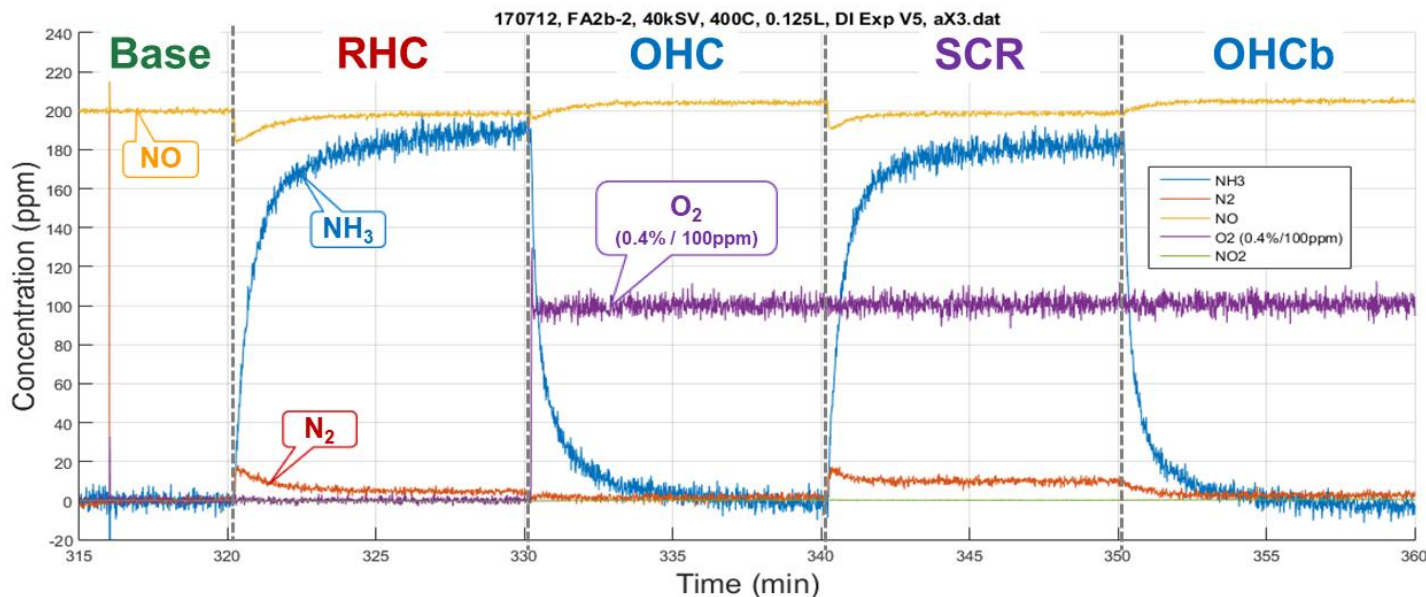

- Dynamic NH<sub>3</sub>-coverage inhibition can induce CI in Fe/SCR catalysts
  - Observe at both SCR onset and termination
  - More apparent at higher coverage; i.e., lower temperatures
- Cu/SCR CI does not follow these trends
  - Only apparent at SCR onset and not at termination
  - More apparent at higher temperatures where NH<sub>3</sub> coverage is lower
- Origin of Cu/SCR CI is different from that of Fe/SCR CI
  - Cu/SCR CI is apparently not due to NH<sub>3</sub>-coverage inhibition

# Conversion Inflections may provide Measure of Catalyst State

- CI transients vary systematically with conditions and catalyst state
  - Exist deeper into catalyst with lower conversion; due to T, composition, age, etc.
  - Observed above a consistent temperature-dependent NH<sub>3</sub> threshold
- Relevant to catalyst-state assessment, control & OBD
  - E.g., correlate CI timing or location with aged state
  - Feedback for adjusting urea dosing, or model-based control parameters

# 5-Step Experimental Protocol for Studying Onset Transients

- Individual RHC, OHC & SCR transitions investigated

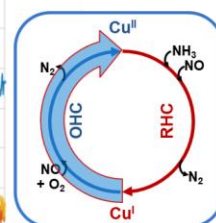

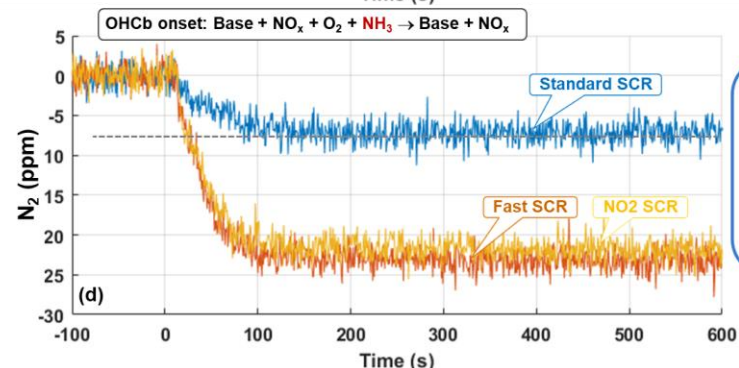

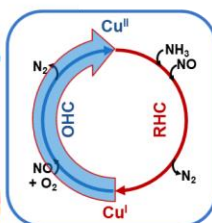

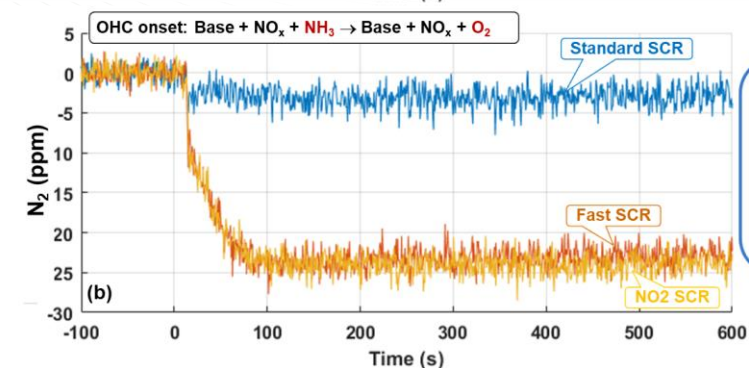

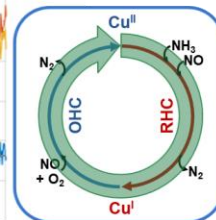

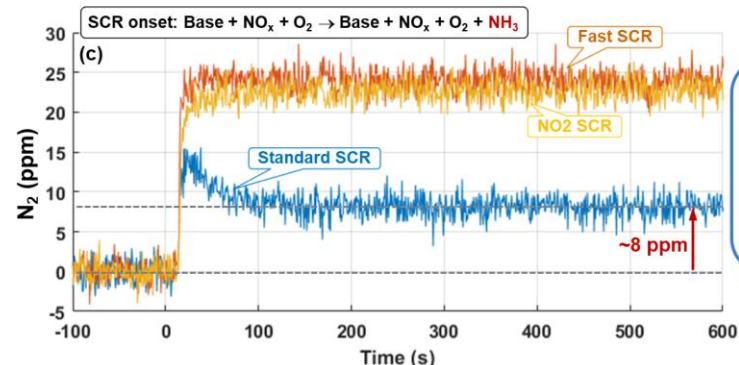

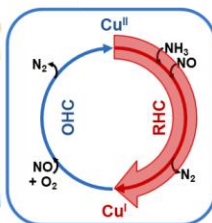

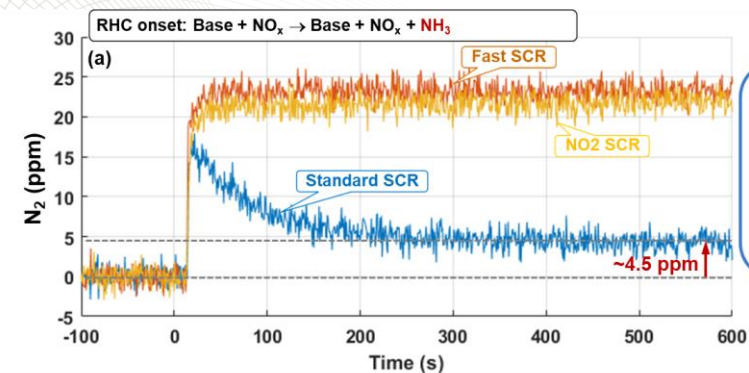

- Step 1 - **Base**: 5% H<sub>2</sub>O + 200ppm NO<sub>x</sub> in Ar
- Step 2 - **RHC**: Base + 200ppm NH<sub>3</sub>
- Step 3 - **OHC**: Base + 0.4% O<sub>2</sub>
- Step 4 - **SCR**: Base + O<sub>2</sub> + 200ppm NH<sub>3</sub>
- Step 5 - **OHCb**: Base + O<sub>2</sub>

- Different SCR mixtures investigated

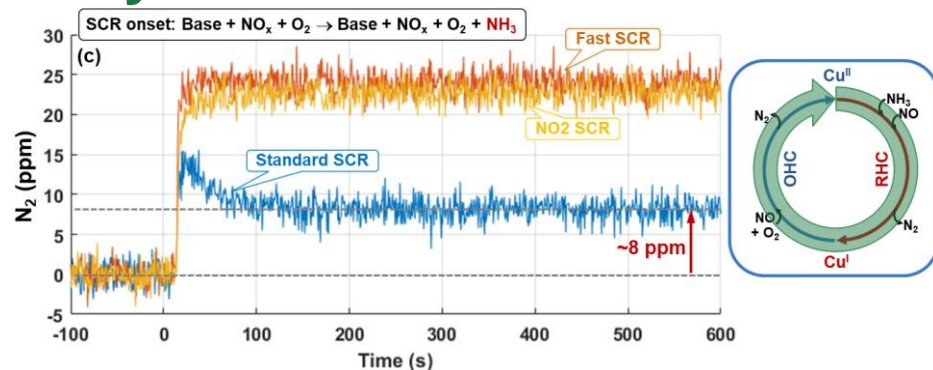

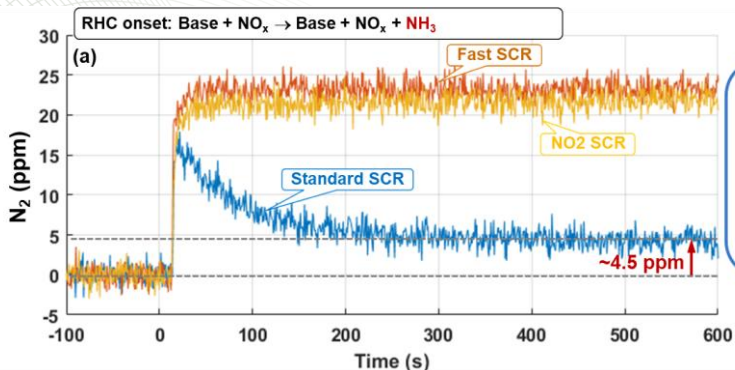

- Standard, Fast & NO<sub>2</sub>
- 200ppm NO<sub>x</sub>

- Commercial CHA SCR
- Field Aged: FA-2b
- 400°C
- 1/8L
- 40k SV

# Measured Half-Cycle Onset Transients

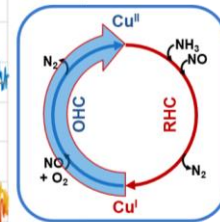

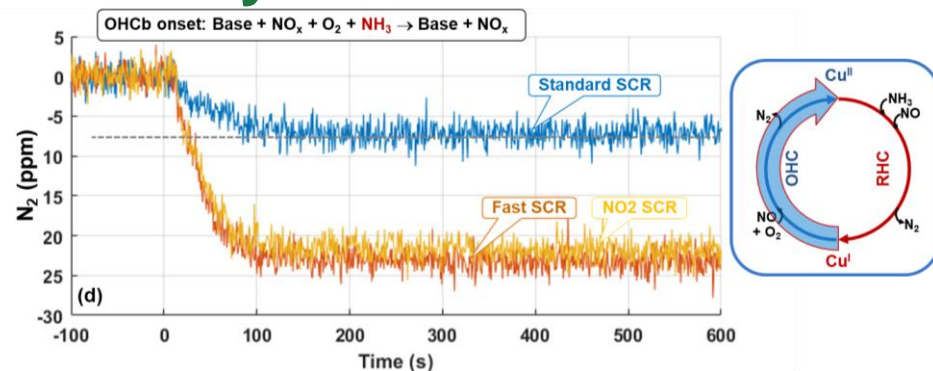

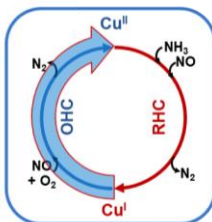

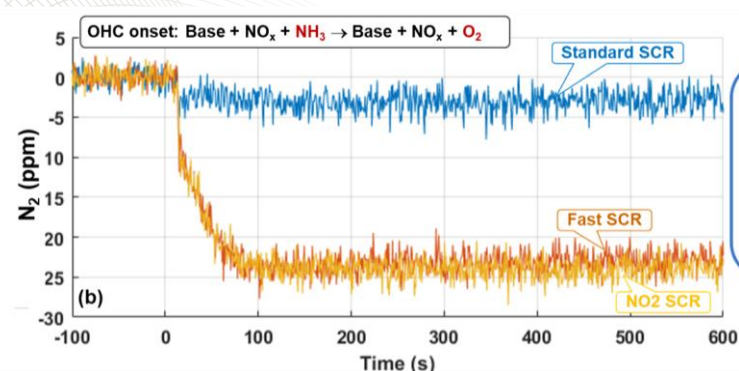

# Measurements of Individual Half-Cycle Onset Transients

- 5-Step Experimental Protocol designed to study half-cycle onset transients & CI
  - Allows individual and combined half cycles to be probed (see Tech. Backup Slides)
- Standard SCR Onset Transients
  - RHC onset shows CI
    - Initial fast step-like transients indicates native RHC rate
    - Conversion degrades over  $\sim 200$ s as  $\text{Cu}^{\text{II}}$  is depleted
    - Non-zero SS due to contaminant or bulk oxygen driving OHC
  - For SCR onset
    - CI is smaller & faster, and SS conversion is greater
    - both half-cycles are active
- $\text{NO}_2$  & Fast SCR Onset Transients
  - Identical, fast, step-like transients without CI
    - Suggests OHC occurring via  $\text{NO}_2$ , and  $\text{O}_2$  not participating
- OHC transients offer additional insights (see Tech. Backup Slides)

# Measurements of Individual OHC Half-Cycle Onset Transients

- OHC Onset Transients

- Starts from maximum [Cu<sup>I</sup>] following RHC step
  - [Cu<sup>I</sup>] greater than at OHCb start
  - Causes greater step-like onset vs. OHCb transient
- NO<sub>2</sub> & Fast SCR transient are identical
  - Initially step-like, then slow over ~100s as Cu<sup>I</sup> is depleted
- Standard SCR show NO CI (see 5-Step Protocol figure)
  - Signal-to-noise is too small to resolve similar N<sub>2</sub> CI

- OHCb Onset Transients

- These follow SCR, and thus start from lower [Cu<sup>I</sup>] initial condition
- Slower Standard SCR transient (~150s) vs. NO<sub>2</sub> & Fast SCR (~100s)
  - Different OHC mechanism & kinetics for O<sub>2</sub>- vs NO<sub>2</sub>-driven OHC
- NO<sub>2</sub> & Fast SCR transients are identical as with OHC
  - Suggests OHC driven by NO<sub>2</sub>, and O<sub>2</sub> is practically inert

# Half-Cycle based Model for Standard & Fast SCR

## Standard SCR

$$r_{\text{RHC}} = k_{\text{RHC}} \cdot [\text{Cu}^{\text{II}}] \cdot [\text{NO}] \cdot (\theta_{\text{NH}_3})^{\sim 0} \cong k_{\text{RHC}} \cdot [\text{Cu}^{\text{II}}] \cdot [\text{NO}] \quad (2)$$

$$r_{\text{OHC}} = k_{\text{OHC}} \cdot [\text{Cu}^{\text{I}}]^2 \cdot [\text{O}_2] \cdot [\text{NO}] \quad (4)$$

## Fast SCR

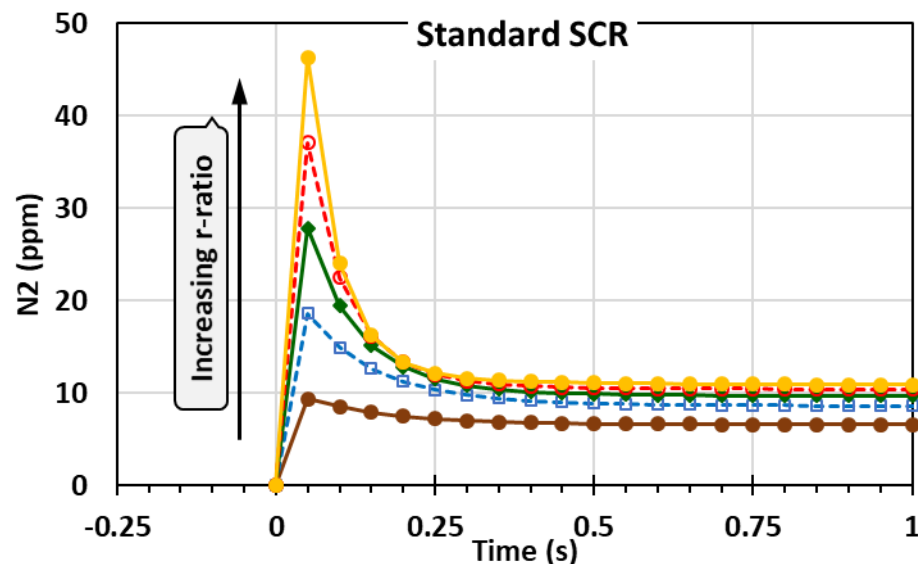

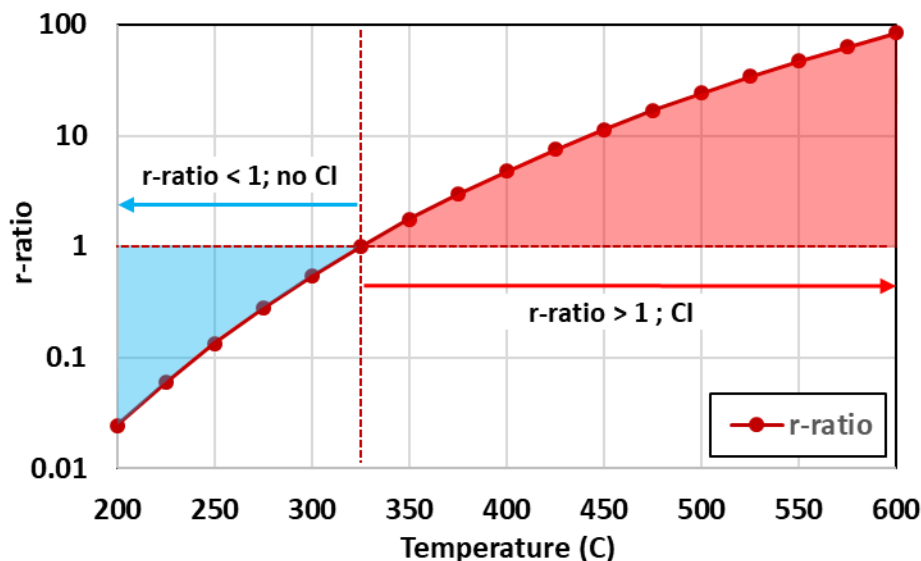

$$r_{\text{RHC}} = k_{\text{RHC}} \cdot [\text{Cu}^{\text{II}}] \cdot [\text{NO}] \cdot (\theta_{\text{NH}_3})^{\sim 0} \cong k_{\text{RHC}} \cdot [\text{Cu}^{\text{II}}] \cdot [\text{NO}] \quad (2)$$

$$r_{\text{OHC}} = k_{\text{OHC}} \cdot [\text{Cu}^{\text{I}}] \cdot [\text{NO}_2] \quad (7)$$

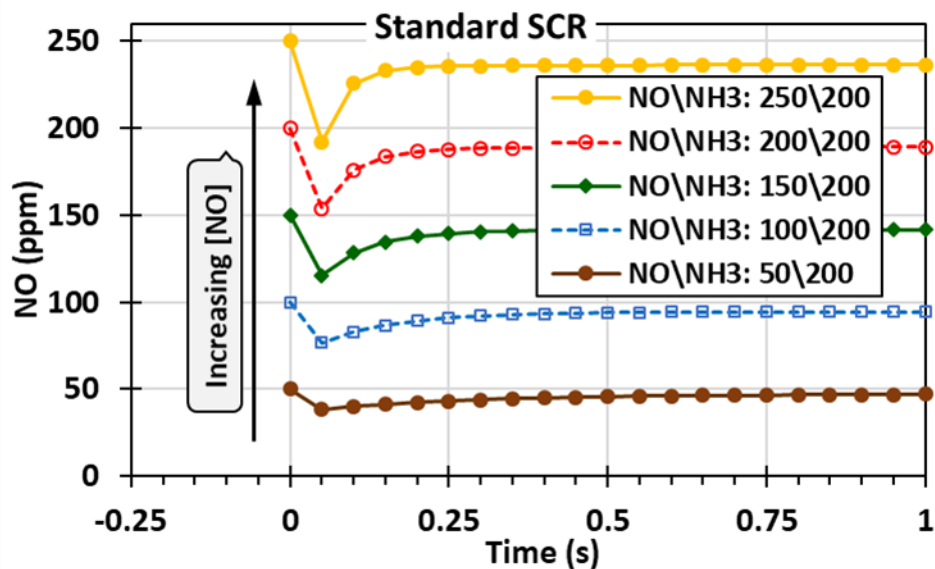

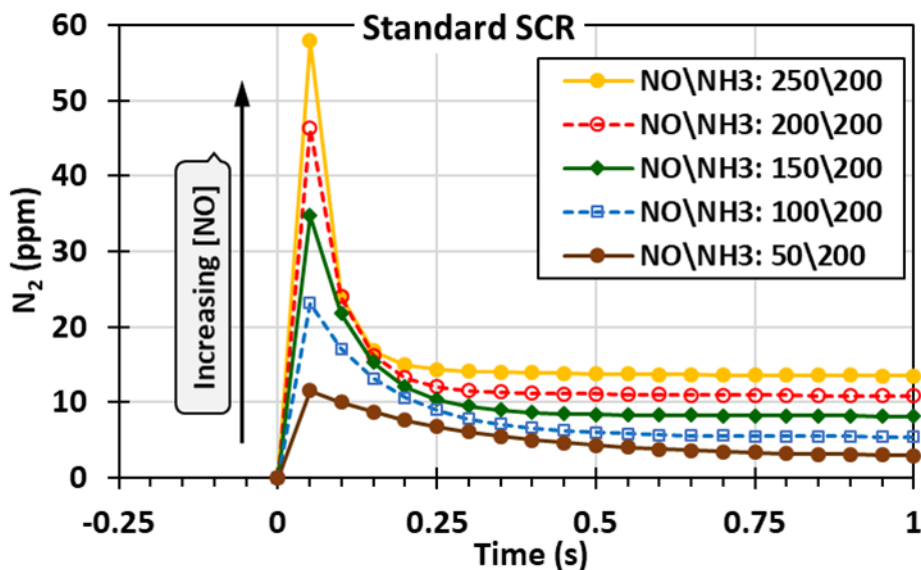

# Global Model Predicts Consistent CI Nature & Trends

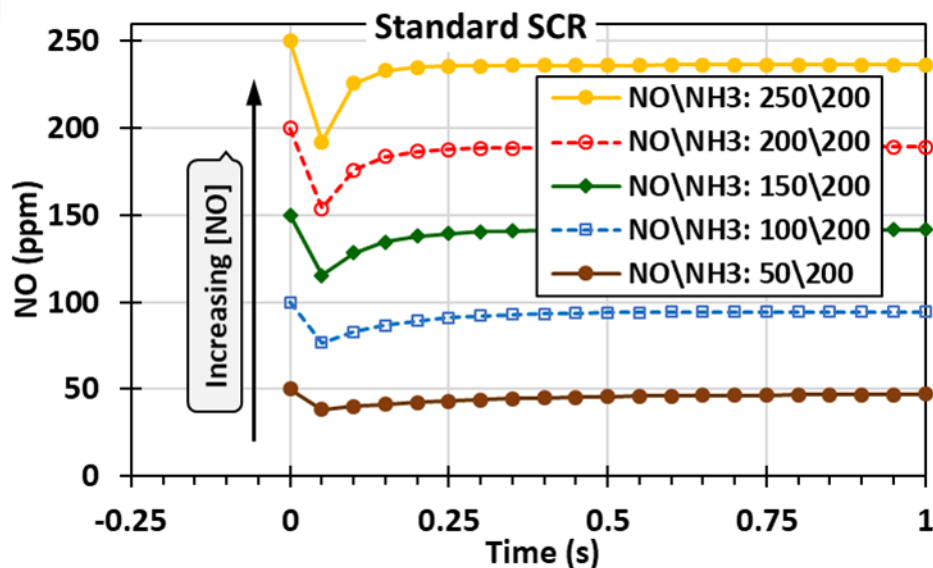

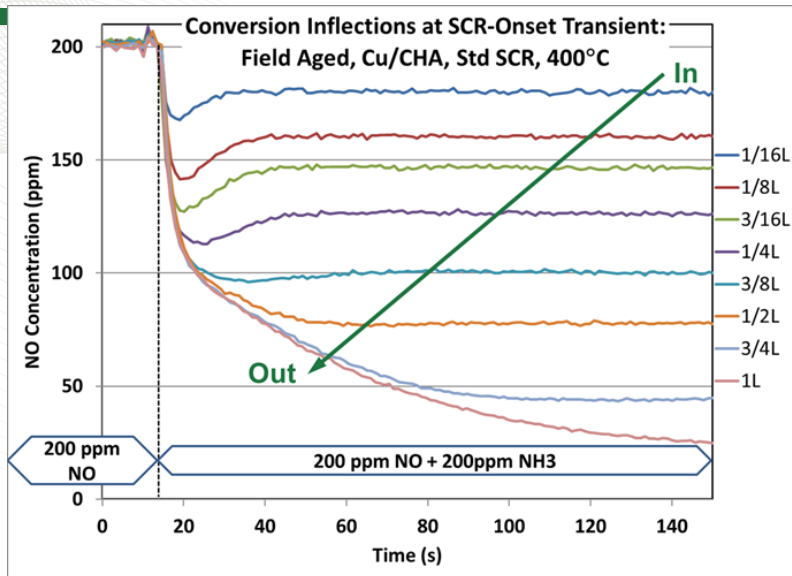

- Half-cycle model exercised to study how kinetic parameters influence CI
  - Model details shown in Tech. Backup Slides
- Ratio of half-cycle rates ( $r\text{-ratio} = r_{\text{RHC}} / r_{\text{OHC}}$ ) increases with temperature
  - CI should be observed when  $r\text{-ratio} > \text{unity}$
  - Unity crossing point tuned with RHC & OHC pre-exponential factors
- CI becomes more distinct with increasing r-ratio
  - Taller peak, faster tail
  - SS conversion increases with r-ratio
  - **Temperature trend is consistent with experimental observations**
- **CI nature varies with half-cycle kinetic parameters**

# Global Model – CI varies with NO Concentration

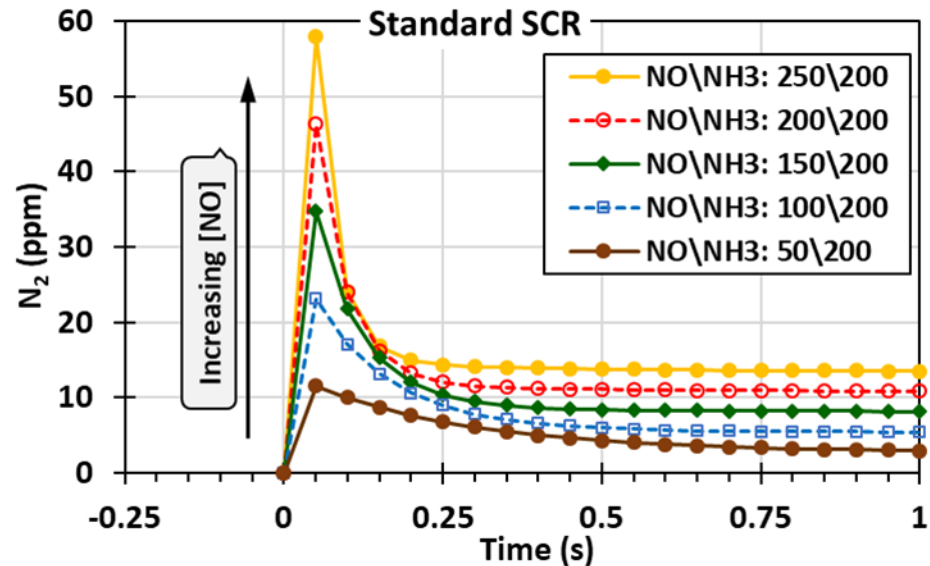

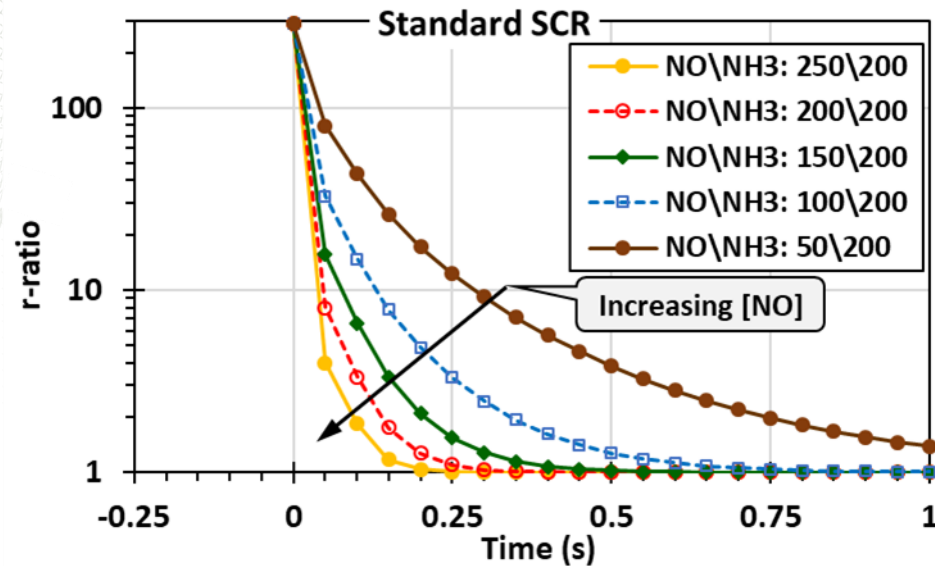

- Varying [NO] at constant 200ppm NH<sub>3</sub>
  - CI independent of [NH<sub>3</sub>], (zeroth order in [NH<sub>3</sub>], see Tech. Backup Slides)
- CI becomes increasingly distinct with increasing [NO]
  - Similar for both N<sub>2</sub> & NO CI

# Global Model – CI varies with NO Concentration

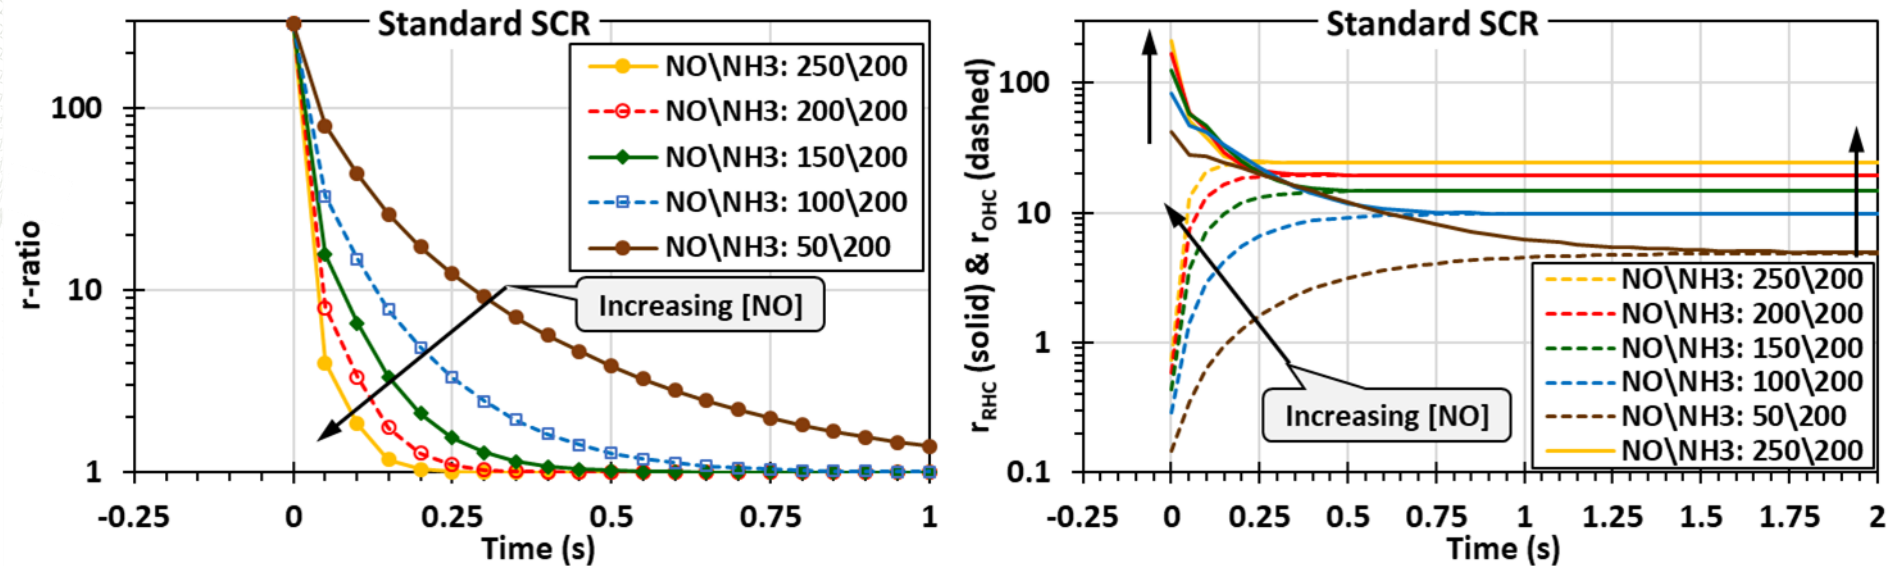

- Varying [NO] at constant 200ppm NH<sub>3</sub>
  - CI independent of [NH<sub>3</sub>], (zeroth order in [NH<sub>3</sub>], see Tech. Backup Slides)
- CI becomes increasingly distinct with increasing [NO]
  - Similar for both N<sub>2</sub> & NO CI
- ***NO CI trends consistent with measured trends along catalyst axis***
  - Greatest CI at catalyst front
  - CI degrades along catalyst as NO-conversion progresses
- ***Spatiotemporal measurements may be used to tune a global model***
  - Determine half-cycle kinetic parameters from fitting model to measurement data

# Global Model – Half-Cycle Rates vary with NO Concentration

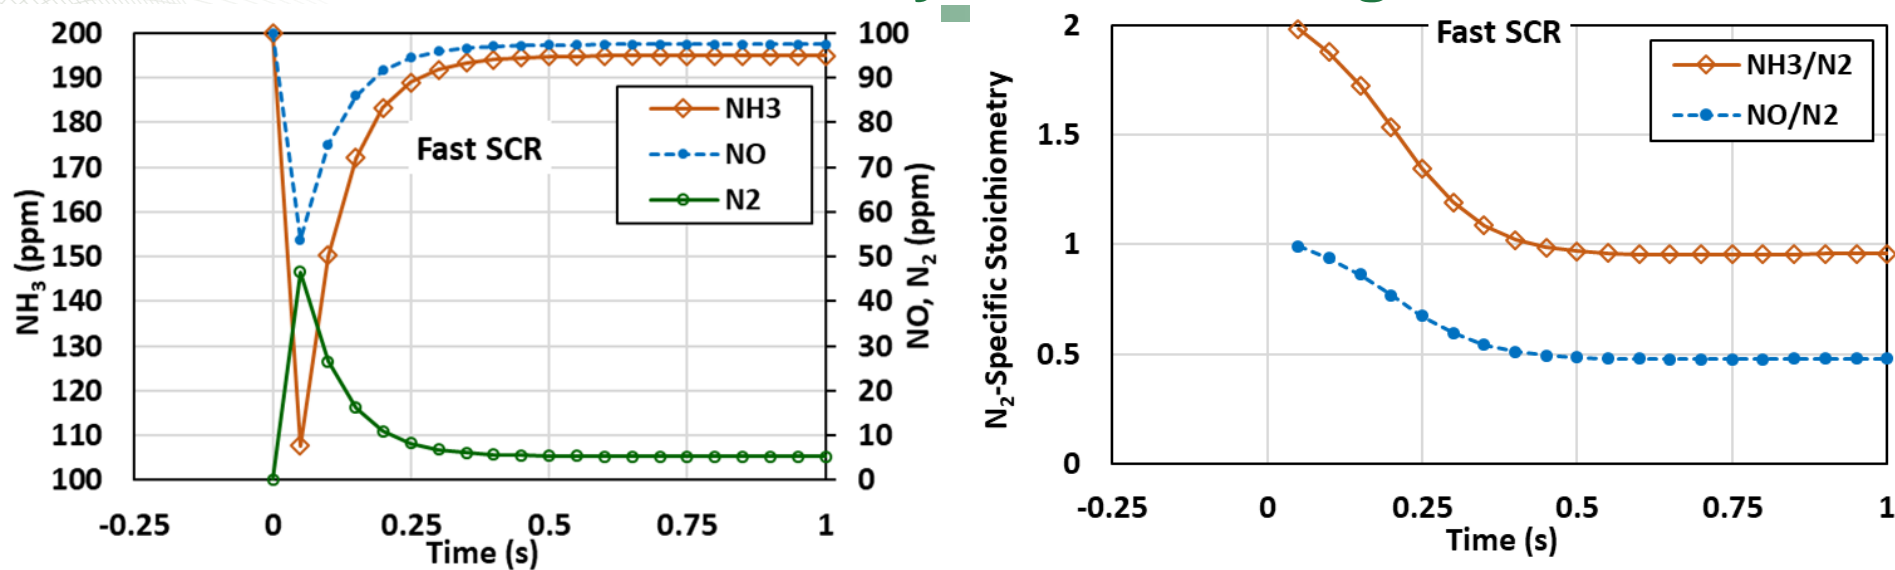

- r-ratio transient becomes faster with increasing [NO]
  - Distinct CI needs both r-ratio>1 and fast r-ratio transient

# Global Model – Half-Cycle Rates vary with NO Concentration

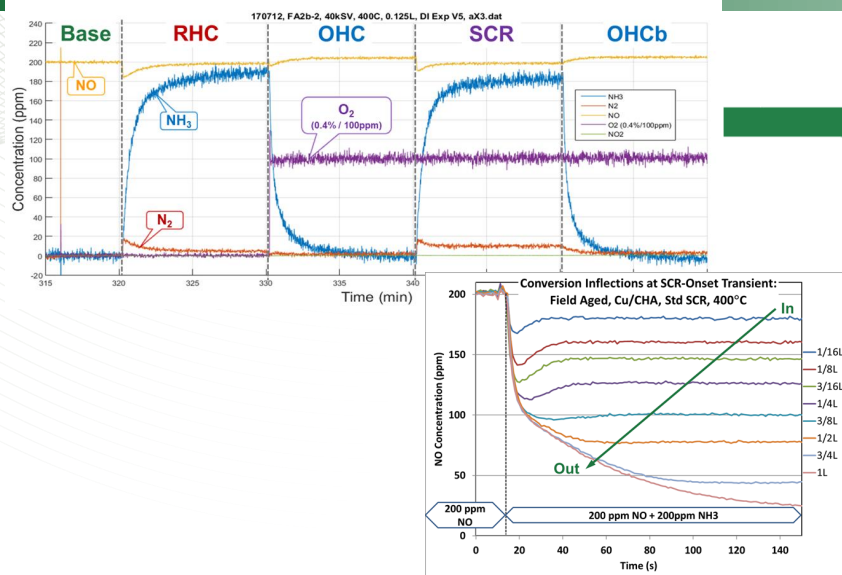

- r-ratio transient becomes faster with increasing [NO]
  - Distinct CI needs **both**  $r\text{-ratio} > 1$  **and** fast r-ratio transient
- RHC & OHC rates converge at steady state
  - Mainly due to RHC slowing
    - Relatively small  $r_{OHC}$  increase associated with increasing  $Cu^I$
  - Greater SS conversion & rates with increasing [NO] (*consistent with SpaciMS*)
  - Rate transient is greater when initial difference is greater
  - **Half-cycle rate behavior is consistent with conceptual model**
- **Model-based studies help advance CI understanding and nature**

# Global Model – Stoichiometry Varies Through CI Transient

- Model predicts CI for NO, NH<sub>3</sub> and N<sub>2</sub>
- CI leading edge reflects RHC stoichiometry
  - RHC:  $\text{Cu}^{\text{II}}(\text{OH})(\text{NH}_3) + 2 \cdot \text{NH}_3 + \text{NO} \rightarrow \text{Cu}^{\text{I}}(\text{NH}_3)_2 + \text{N}_2 + 2\text{H}_2\text{O}$
- Steady state reflects Net Fast SCR stoichiometry
  - Net Fast SCR:  $2 \cdot \text{NO} + 2 \cdot \text{NO}_2 + 4 \cdot \text{NH}_3 \rightarrow 4 \cdot \text{N}_2 + 6 \cdot \text{H}_2\text{O}$
- Stoichiometry transient reflects half-cycle balancing
  - As rates converge impact of the individual half cycles balance
- Generally similar results for Standard SCR (see Tech. Backup Slides)
- **Technique can be use to validate model formulation**

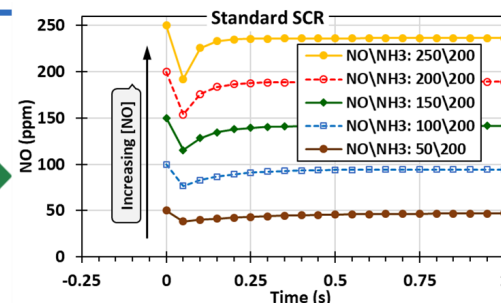

# Methodology for Formulating & Validating SCR Redox Model

$$r_{\text{RHC}} = k_{\text{RHC}} \cdot [\text{Cu}^{\text{II}}] \cdot [\text{NO}] \cdot (\theta_{\text{NH}_3})^{\sim 0} \cong k_{\text{RHC}} \cdot [\text{Cu}^{\text{II}}] \cdot [\text{NO}]$$

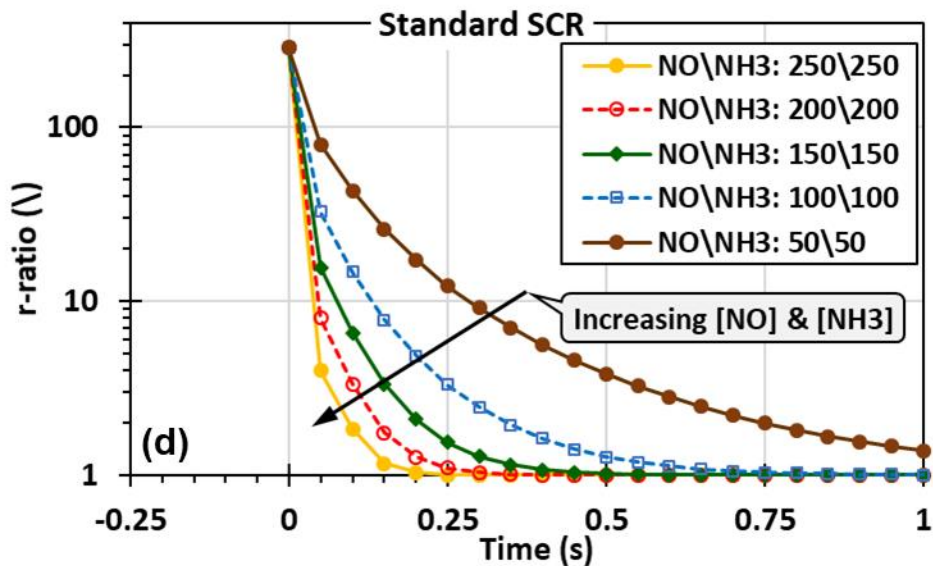

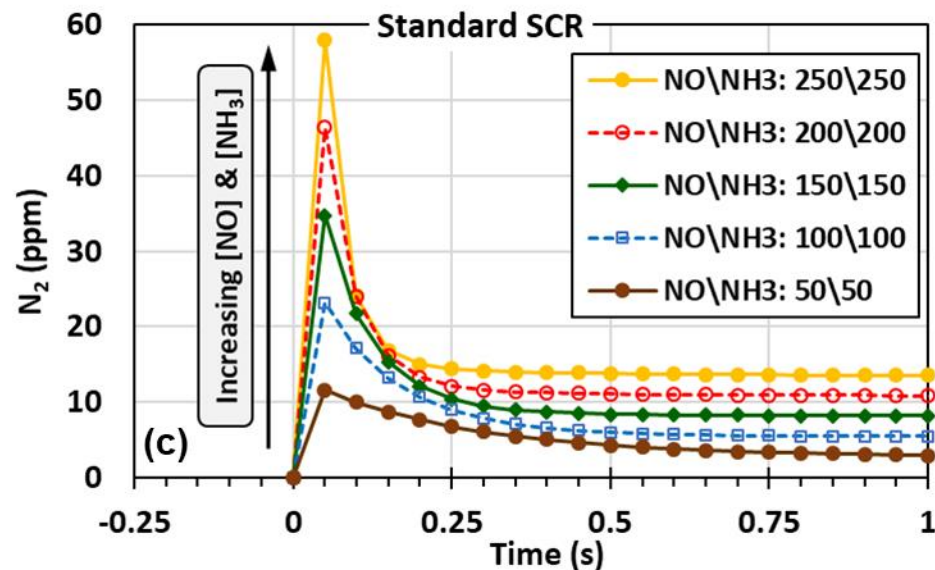

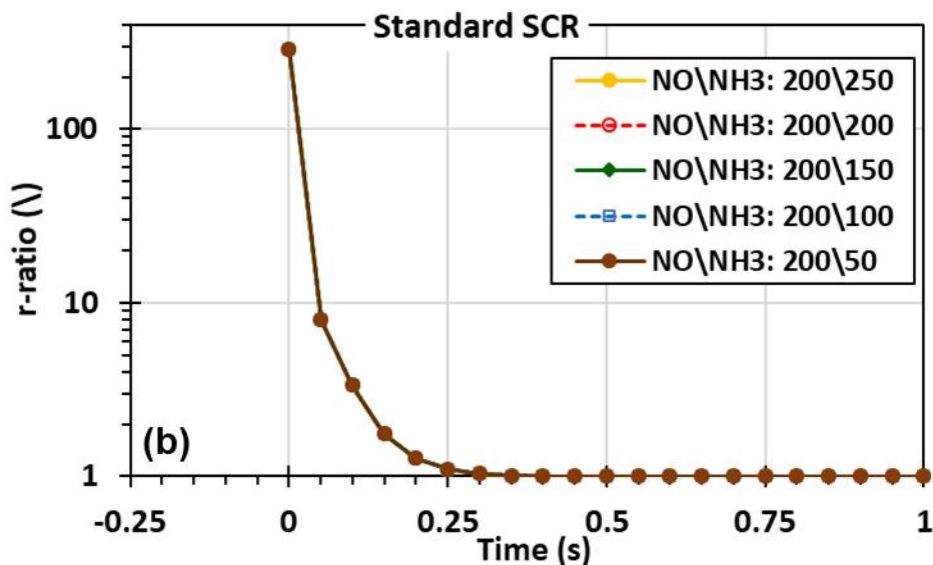

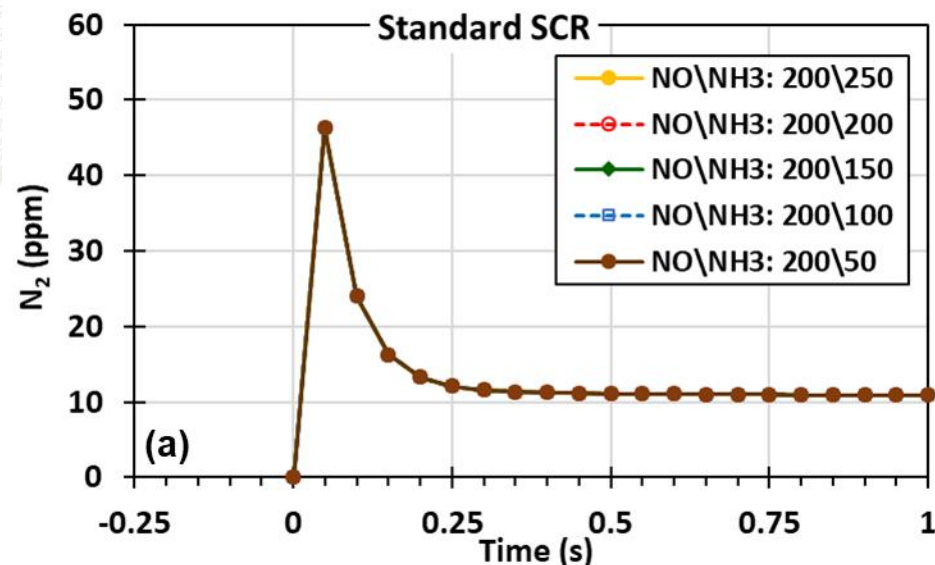

$$r_{\text{OHC}} = k_{\text{OHC}} \cdot [\text{Cu}^{\text{I}}]^2 \cdot [\text{O}_2] \cdot [\text{NO}]$$

- Step-response experiments to characterize CI & onset transients
  - Range of temperatures and concentrations
  - 5-Step Protocol to investigate individual & combined half cycles
  - **Our measurements are the first to resolve half-cycle rate balancing**
- Formulate global SCR model based on the two half cycles
  - CI & transient nature varies with model formulation & kinetic parameters
    - Examples show broad dependence of transient performance on model parameters
    - Model CI trends are consistent with measurements
  - **Our half-cycle model is the first to show this transient SCR nature**
- Use data to formulate, tune & validate the global SCR model – **Next Steps**

# Global Model – CI varies with [NO] but not with [NH<sub>3</sub>]

# Global Model – Stoichiometry Varies Through CI Transient
